

Remark N° 1
Human and Social Environment
Baseline

AES Gener draws a veil over the influence of the PHAM project in this area. It should call on studies validated by a renowned academic institution to assess the number of jobs to be lost due to effects caused by the Project. Please specify the number of jobs that would cease to be available in sectors such as tourism, aggregates, commerce, transport, and other associated areas, broken down by sector.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term

mutually beneficial relationships between the project and its surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**.

CAL.05 Promoting entrepreneurship

The company has agreed to use its **Fundación Maitenes** foundation to set aside an **annual fund over a 10 year period starting in 2010**, to support local residents who formulate tourism development business plans for implementation in the area. These projects will be financed through funds open for competitive tenders; submissions will be evaluated on their own merit by a council of community representatives, which will select which projects will be funded.

The initiative to be implemented by the Fundación Maitenes may be linked to projects in progress run by public institutions and services in the district, related to the two lines of action that the foundation has agreed to support. This linkage may help to strengthen state-run initiatives and foster sustainability over the course of time for the actions supported by the foundation, during the period in which the program is active.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. In parallel, the study investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 2 Ethnographic Study

The Project Owner must present a serious and unbiased study addressing all social and economic productive activities undertaken in the Maipo Valley areas that would be directly or indirectly affected by the Project.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

CAL.02 Education

A goal of the Maitenes Foundation relates to education for children and young people against the backdrop of the natural environment (for more information on the goals and achievements of the Foundation, see Annex 26 of the EIS).

Gener firmly believes that contributions to the technical and vocational education and training of young people must keep sight of real employment possibilities. Therefore, as a first initiative it has earmarked resources for an education improvement project in the district, which will contribute to establishing education management for the restructuring of the school curriculum and professional technical capacity building, taking into account the features needed to boost local employability. Based on information and recommendations from this study, Gener, acting through the Maitenes Foundation, will undertake a Capacity Building for Employability Program fundamentally oriented towards those whose family, social, or economic situation has barred them from completing their education and training, or acquiring the skills needed in order to find work. **CAL.03 Sports and leisure areas**

In order to avoid the loss or modification of land usage patterns, changes in usage, or loss of income associated with potential reduction in perceptions of the value of the surrounding areas, in terms of the provision of leisure, tourism, education, and other related services, the Project has developed a suite of measures that aim to minimize its environmental impact, so as to preserve the features that lead to the high perception of value of the area among residents, visitors, and tourists. These measures include: installation of most works in underground settings, thus minimizing their visual impact; the preservation of ecological flow rates in rivers and streams; and revegetation and reforestation of affected areas.

Similarly, the Project has enacted a suite of further measures to minimize interference with traditional livestock industries, as well as tourism and mountain/river sports.

In this way, the Project has taken all steps necessary in order to mitigate impacts on the environment, which will allow the area to retain the characteristics that make it so attractive for open-air education, tourism, and leisure activities. This will allow the project to operate alongside existing activities conducted in this area.

A wide-ranging suite of monitoring activities will be implemented to verify the effectiveness of the environmental measures (for more information, see **Chapter 8 of the EIS**). In parallel, and in order to verify that the Project does not affect cultural land usage patterns, applicable indices will be included for monitoring under the Social Indicator Monitoring (SIM) program.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **CAL.05 Promoting entrepreneurship**

The company has agreed to use its **Fundación Maitenes** foundation to set aside an **annual fund over a 10 year period starting in 2010**, to support local residents who formulate tourism development business plans for implementation in the area. These projects will be financed through funds open for competitive tenders; submissions will be evaluated on their own merit by a council of community representatives, which will select which projects will be funded.

The initiative to be implemented by the Fundación Maitenes may be linked to projects in progress run by public institutions and services in the district, related to the two lines of action that the foundation has agreed to support. This linkage may help to strengthen state-run initiatives and foster sustainability over the course of time for the actions supported by the foundation, during the period in which the program is active.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. In parallel, the study investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 3
Impact on Residents

The Project Owner must provide the local community with concrete guarantees regarding employ opportunities to be made available for those who are out of work or looking for better jobs, backing up these guarantees with legally valid documentation.

Thematic responses

Specific response

The Project Owner is unable to provide guarantees of employability, given that:

1. hiring activities will be undertaken by the works contractors
2. the suitability of each applicant must be assessed by the corresponding contracting party, in accordance with its requirements

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

SOC.01.01 Requirements

In view of the characteristics and scale of the Project, personnel with specific qualifications will be required for the operation and maintenance of plant machinery and equipment, during the operations phase. Conversely, during the Project Construction Phase, it is projected that labor requirements will create jobs not only for mining workers, but also for machinery operators, drivers, and both skilled and unskilled construction personnel, the latter working mainly as day laborers and assistants.

The population of the Project's area of direct influence has been found to possess levels of training and specialization (occupation as defined under the CIU code) that shall permit them to access both skilled and unskilled work positions created by the Project.

Remark N° 4 Labor

The Project Owner should describe the types of position to be filled by local residents, indicating quality and quantity broken down by age, sex, type of qualifications, and job requirements. In particular, please specify the quantity and type of employment to be made available to young people in the area, and the quantity and type of employment to be made available to women heads of households.

In line with this breakdown, the Project Owner should also specify the start date and exact duration of employment to be provided.

Thematic responses

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157

Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

SOC.01.01 Requirements

In view of the characteristics and scale of the Project, personnel with specific qualifications will be required for the operation and maintenance of plant machinery and equipment, during the operations phase. Conversely, during the Project Construction Phase, it is projected that labor requirements will create jobs not only for mining workers, but also for machinery operators, drivers, and both skilled and unskilled construction personnel, the latter working mainly as day laborers and assistants.

The population of the Project's area of direct influence has been found to possess levels of training and specialization (occupation as defined under the CIIU code) that shall permit them to access both skilled and unskilled work positions created by the Project.

SOC.01.02 Working conditions

To date no schedule exists specifying labor requirements for the full duration of the construction phase. Detailed information specifying jobs created under average and peak labor requirements, broken down by labor requirement dynamics for each encampment, will only be available once the Project Owner has tendered the works contracts.

During the operations phase, it is expected that personnel requirements will amount to approximately 80 positions available, required for power plant operations and maintenance activities. Unlike work positions created during the construction phase, the jobs created in the operations phase will be permanent (EIS, Chapter 6, Section 6.4.2.4).

The Project Owner will provide for coordination between the construction works contractors, the Labor Brokerage Office, and the Municipality of San José de Maipo, regarding local labor required and jobs sought. The PHAM has accepted a commitment to incentivize works contractors to prioritize local contracting of labor required.

No prior training is planned in advance of the Construction Phase. However, such training will form part of the programs implemented in the more advanced phases of the project.

Remark N° 5 Impact on Production Activities and Users of Sanitary Services

Imbalance in the sedimentological dynamics of the Maipo River caused by the Project brings about a risk affecting a wide range of production activities and users in the Metropolitan Region, such as: sand producers, irrigation users, the Ministry of Public Works, and the company Aguas Andinas.

Thematic responses

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López and Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river.

In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in

flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level.

It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be identical to those currently observed.

It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times of the year flow rate in the Maipo River watercourse drops significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake owned by Aguas Andinas, etc.

Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual

abstraction rate at these intakes varies between 78 and 164 m³/second.
This situation clearly explains the high level of perturbation observed in the behavior

of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years.

It is for this reason that the Project Owner asserts that its activities will have no impact on the current situation in the sand extraction sites located on the Maipo River.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service.

Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. The study also investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 6 Impact on Production Activities: Tourism

The Project is designed to minimize impact on tourism infrastructure, with point classifications and in relation with highway-related issues. This activity's real-world contribution to the District must be identified, along with the way in which it will be affected by reductions in flow rates, damage to ecosystems, access to mountain areas, impact on the landscape from power transmission lines.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally

complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's

high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plant (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **ELE Electrical Installations**

The electrical installations presented in the EIS comprise the substation, to be located in the El Sauce area, the characteristics of which are to be found in **Annex 27 of the EIS**; given that the electricity transport layout (cabling and towers) is to be presented to the Environmental Impact Assessment System once all background information is available.

ELE.03 Transmission lines

In view of the project's location, close to Santiago, it is expected that the distance covered by the definitive cabling layout will be short, involving a minimum of sectors not subject to prior intervention. With regard to the specific location of the cabling layout, plans call for the use of the existing high tension power line used by the Queltehues, Volcán, and Maitenes Plants.

Once the layout of the high tension power line has been defined, the Project Owner will submit this plan to the Environmental Impact Assessment System, in accordance with legislation in force. In line with the development of the Compliance Plan for environmental legislation applicable to the Project, the General Regulations applicable in this instance are indicated below:

Decree with Force of Law N°4, dated 05 February, 2007, setting forth the Recast, Coordinated, and Systematized Text of the General Law on Electrical Services.

The General Law on Electrical Services governs the generation, transmission, distribution, and regimen of concessions and tariffs applicable to electrical energy, and the functions of the State with regard to these areas.

Supreme Decree N° 327, Regulations Regarding the General Law on Electrical Services

The Regulations Regarding the General Law on Electrical Services establish, in their 8th Article, that hydroelectric power plants, electrical substations, and transmission lines may be installed without making a request for a concession, when the interested party wishes. These concessions may be provisional (in order to study projects) or definitive. A definitive concession is granted by a supreme decree issued by the Ministry of the Economy, by order of the President of the Republic. Permits relating to electrical installations that do not require concessions are granted by the corresponding Municipal Governments.

For further information and analysis on the aforementioned regulations, with regard to the Project, as well as in terms of general aspects, compliance, and regulatory bodies, please see **Sections 3.1.6 and 3.1.7 of Chapter 3 of the EIS**, where more detailed versions of this information can be found.

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3**, and **Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neopteris curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Liolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed

will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor.

(see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

TUR Tourism

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.01 River sports

During the operations phase, the activities of the PHAM shall not directly or indirectly interfere with tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. Furthermore, the PHAM shall have no significant effect on boating activities on the Maipo River as a result of reductions in river flow rate; an analysis is presented in Annex 17 of the Addendum modeling a number of hydrological scenarios (1), concluding that the PHAM shall not affect the current situation in rafting and kayaking activities conducted in the area between San Gabriel and San José de Maipo.

In order to establish an analysis comparing the current Maipo River boating situation with predictions for the situation with the Project operational, the variables of flow rate, river width, and water depth were modeled, as valid indices to establish conditions for boating activities on the Maipo River.

This analysis showed that the Project shall not interfere with tourism activities conducted on the Maipo River, in view of estimates that in a dry year, the magnitude of variations in flow rate and water depth will not cause interference with boating activities.

For more information, see **Annex 17 of Addendum 1**.

- (1) The hydrological analysis used to evaluate reductions in flow rate is based on a statistical record going back 50 years, thus ensuring that seasonal and annual variations are incorporated into the analyses conducted.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector.

This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

TUR.03 Visual impact

The Project Owner has conducted a study to characterize the landscape of the area in which

the Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and continue throughout the working life of the Project. A qualitative methodology is used to study these effects, whereby the first phase consists of identifying sources of visual impact, and the second phase relates to identifying and classifying environmental impacts.

As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention.

As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access roads.

For further information on the methodology used for landscape impact assessment, see **Chapter 6, Section 6.1.4.10 of the EIS, and Annex 17 of Addendum 1.**

Remark N° 7

Impact on Production Activities: Tourism

What plans exist for the mitigation of the impact that the Project shall cause for tourists during the operations phase, through increases in journey times or increased waiting periods at intersections? The project owner should calculate the percentage of Santiago residents who regularly visit the Maipo Valley and who shall stop visiting as a result of annoyances caused by the Project.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents.**

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19.**

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1.** The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS.**

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfal, Aucayes, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions.

The Project's has been designed and engineered to include a suite of measures for the optimization of the construction of new roads; for further information on these measures, see **Chapter 2, point 2.3.2.5 of the EIS.**

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in

these areas, demonstrating that no interference will arise, due mainly

to the following factors:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

VIA.03 Congestion

When PHAM Project construction activities begin, there will be an increase in road traffic movements in the immediate surroundings of the work area. This vehicle movement will be related mainly to the transport of supplies and machinery to the works installations, transport of excavation spoil to muck deposition sites, and, to a lesser extent, the transport of personnel to the work sites. For more information on traffic flow increases resulting from the Project, see **Chapter 2, section 2.4.1, part E, Annex 14 of the EIS, and Annexes 9 and 14 of Addendum 1.**

The PHAM highway impact analysis takes into account all works and activities under the Project, including the transport of supplies, machinery, and personnel. According to modeling studies, it is predicted that there will be no significant impact on highway usage (levels of saturation of new and existing roads and intersections). For more information on the Project's road operations, measurements used and models derived, see **Annexes 9 and 15 of the Addendum.**

Additionally, increases in noise emissions are analyzed in **Section 6.4.1.2 of the EIS.**

Notwithstanding the above, it is assumed that, given that certain construction activities shall be conducted at the same times that other road users wish to make use of certain sections of specific roads, a certain level of annoyance may be caused, and for this reason the PHAM has adopted a number of control and mitigation measures, indicated in **Chapters 6 and 2 of the EIS** and in **Annex 14 of the EIS, as well as Annexes 9 and 17 of Addendum 1.**

It is considered likely that, in view of the predominance of the tourist industry in the local economy of the district of the Maipo Valley, a certain level of annoyance may be caused at certain points and at specific moments, mainly due to conflicts between PHAM road usage and the movements of visitors. As indicated in the EIS Baseline Study, this is an area where tourists come to enjoy walks and peace and quiet, on weekends and holidays. In particular, there are 2 specific tourism attractions located in the same areas as site installations: the El Yeso and the Alto Volcán area, where special measures shall be taken, as specified in **Chapter 6 of the Project EIS.**

Additionally, **Annex 32 of the EIS** specifies emergency procedures to be adopted in the event of transport accidents caused by project vehicles.

Remark N° 8 Mitigation, Restoration, and Compensation Measures

What concrete social benefits will AES Gener contribute to the local community, given that it shall make commercial use of the valley's water and landscape resources? Indicate direct benefits in the fields of health, housing, and education.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

CAL.02 Education

A goal of the Maitenes Foundation relates to education for children and young people against the backdrop of the natural environment (for more information on the goals and achievements of the Foundation, see Annex 26 of the EIS).

Gener firmly believes that contributions to the technical and vocational education and training of young people must keep sight of real employment possibilities. Therefore, as a first initiative it has earmarked resources for an education improvement project in the district, which will contribute to establishing education management for the restructuring of the school curriculum and professional technical capacity building, taking into account the features needed to boost local employability. Based on information and recommendations from this study, Gener, acting through the Maitenes Foundation, will undertake a Capacity Building for Employability Program fundamentally oriented towards those whose family, social, or economic situation has barred them from completing their education and training, or acquiring the skills needed in order to find work. **CAL.03 Sports and leisure areas**

In order to avoid the loss or modification of land usage patterns, changes in usage, or loss of income associated with potential reduction in perceptions of the value of the surrounding areas, in terms of the provision of leisure, tourism, education, and other related services, the Project has developed a suite of measures that aim to minimize its environmental impact, so as to preserve the features that lead to the high perception of value of the area among residents, visitors, and tourists. These measures include: installation of most works in underground settings, thus minimizing their visual impact; the preservation of ecological flow rates in rivers and streams; and revegetation and reforestation of affected areas.

Similarly, the Project has enacted a suite of further measures to minimize interference with traditional livestock industries, as well as tourism and mountain/river sports.

In this way, the Project has taken all steps necessary in order to mitigate impacts on the environment, which will allow the area to retain the characteristics that make it so attractive for open-air education, tourism, and leisure activities. This will allow the project to operate alongside existing activities conducted in this area.

A wide-ranging suite of monitoring activities will be implemented to verify the effectiveness of the environmental measures (for more information, see **Chapter 8 of the EIS**). In parallel, and in order to verify that the Project does not affect cultural land usage patterns, applicable indices will be included for monitoring under the Social Indicator Monitoring (SIM) program.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **CAL.05 Promoting entrepreneurship**

The company has agreed to use its **Fundación Maitenes** foundation to set aside an **annual fund over a 10 year period starting in 2010**, to support local residents who formulate tourism development business plans for implementation in the area. These projects will be financed through funds open for competitive tenders; submissions will be evaluated on their own merit by a council of community representatives, which will select which projects will be funded.

The initiative to be implemented by the Fundación Maitenes may be linked to projects in progress run by public institutions and services in the district, related to the two lines of action that the foundation has agreed to support. This linkage may help to strengthen state-run initiatives and foster sustainability over the course of time for the actions supported by the foundation, during the period in which the program is active.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

**SOC.01 Jobs in the
District**

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

Remark N° 9 Mitigation, Restoration, and Compensation Measures

The provision of a shameful and insufficient annual fund of US\$ 200,000 over a 10 year period starting in 2010, allocated through the Maitenes Foundation, does not resolve any of the Valley's social problems; and nor does it contribute to the mitigation of the company's immense historic debt to the district.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

Remark N° 10 Environmental Monitoring

What is the objective of the Operations Phase Social Indicator Monitoring Program? In what way will it benefit the local community? Why will it be implemented for only 5 years, when the impact of the Project may continue for decades? What indicators will be used to measure the impact of the Project, if baseline information is insufficient in this regard? What institution will provide guarantees that this study is independent and serious?

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. - ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. Details are provided regarding the principal characteristics of

this program in **Chapter 8, Section 8.2.7 of the EIS**, and in **Annex 39 of the EIS**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

OTR Other

This section relates to certain special situations that could not be categorized, or that are linked to specific requests, disqualifications, or situations that feature a clear political component, against either the environmental authority or the Project Owner.

OTR.02 CONAMA

Remark N° 11
Upper Maipo Basin Area Usage Flow Rate

The company shall not benefit the development of services currently provided in the district (lodging, food, commerce, transport). The encampments and the contractor companies will contract services outside of the district.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

CAL.05 Promoting entrepreneurship

The company has agreed to use its **Fundación Maitenes** foundation to set aside an **annual fund over a 10 year period starting in 2010**, to support local residents who formulate tourism development business plans for implementation in the area. These projects will be financed through funds open for competitive tenders; submissions will be evaluated on their own merit by a council of community representatives, which will select which projects will be funded.

The initiative to be implemented by the Fundación Maitenes may be linked to projects in progress run by public institutions and services in the district, related to the two lines of action that the foundation has agreed to support. This linkage may help to strengthen state-run initiatives and foster sustainability over the course of time for the actions supported by the foundation, during the period in which the program is active.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. In parallel, the study investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 12 1. Water Rights

The Project does not hold concessions for water rights at any abstraction point. A technical report exists, issued by the DGA, that concludes that it would not be possible to make available the water rights requested by Gener because there is no physical availability of water. How can a project of this nature be evaluated if it does not hold the required water rights? Will the Project attempt to take over water rights held by third parties?

Furthermore, a vast number of complaints have been lodged opposing these transfers of rights, in the Upper Maipo area and in the Colorado River, by private individuals, neighborhood groups, irrigation channel user associations, and the company Aguas Andinas.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS**.

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively.

Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 of the year 1990, with Registry Number 202 in the Public Registry of Water Usage Rights (available for examination in **Section V, Question 24, Section vi of the Addendum**).

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in **Chapter 2 of the EIS**.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

Remark N° 13 2. Baseline Study

Given that the project does not hold the water rights that it hopes to use, and that should such rights be granted, the flow rates conceded are as yet unknown, the baseline study is not valid because it is based on suppositions regarding flow rates.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively.

Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 of the year 1990, with Registry Number 202 in the Public Registry of Water Usage Rights (available for examination in **Section V, Question 24, Section vi of the Addendum**).

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of the power plants requires an

ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

Remark N° 14

3. Upper Maipo Basin Area Usage Flow Rate

The Project plans establish a total water abstraction rate in the Upper Maipo Basin area of 27 m³/s. It is not made clear from where this flow rate will be abstracted, given that the maximum statistical monthly average for flow rate in the Yeso River is approximately 11 m³/s. The question is: Does the project plan to make any intervention directly affecting the El Yeso Reservoir?.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.05 Drinking water supply

Construction works and/or activities involved in the project (roads, movement of materials, transport of different products, etc) shall have no effect or impact whatsoever on the quality or security/safety of water supply in the Maipo River system. During the construction phase, Project interventions affecting watercourses shall cause only temporary effects resulting from Earth moving during excavation and other construction activities. This intervention shall affect small areas over short time periods, as it shall last only during the period while these installations are under construction (see **Section 6.4.1.4 of the EIS and Section VII, Question 17, in the Addendum**).

During operations, the PHAM shall not affect the Laguna Negra-Lo Encañado and El Yeso

Reservoir system, which is managed by the company Aguas Andinas S.A, in its capacity as holder of the drinking water concession for Santiago; nor shall the Project affect the operational dynamics of the drinking water supply system. Therefore, the implementation of the PHAM does not imply any impact whatsoever on the supply of drinking water (see **Section I, responses 27 and 29, in the Addendum**).

Furthermore, the water abstracted by the Project shall be returned to the river 5 km upstream of the

Toma Independiente or Independent Intake, operated by the company Aguas Andinas S.A., which abstracts water for drinking water supply to the city of Santiago; therefore, the PHAM shall not affect normal operations of this system. The PHAM shall only affect the delivery point of water in the tributaries of the Maipo River; in other words, water that currently does not drain into the Maipo River shall not be incorporated into that river's total flow.

However, in the event that an incident may arise as a result of an accident during construction, such as accidental spillages or rock falls, the procedures described in the Contingency Plan shall be implemented, consisting of a suite of actions to solve associated problems. This plan is explained in detail in **Chapter 7 of the EIS, Section 7.2.5**.

AGU.05.01 Drinking water quality

The process of hydroelectric power generation does not affect the physical/chemical qualities of water. Additionally, the PHAM does not plan to implement regulation installations that retain sediment. Thirdly, downstream of the discharge point the natural river conditions are maintained with regard to flow rate and physical/chemical properties.

During the construction of installations to be located in watercourses, the free-flowing course of the river is maintained through the construction of diversions through pipes laid along the river course for such purposes, or through channels that divert all flow, allowing free water circulation with no effect whatsoever on quality (see **Section I, Question 28, in the Addendum**).

The Project owner shall not make use of the Lo Encañado Lake or water usage rights owned by Aguas Andinas S.A. for this Project, instead opting to forgo usage of these resources and to replace the role that would have been fulfilled by the Lo Encañado Lake with a forebay located on a widening of the Alfalfa II plant headworks, located in the Alto Aucayes area on the Colorado River Valley (for details, see **EIS 2.2.1**). The Lo Encañado area shall be assigned a status of controlled access area at all times: it shall not be subject to any intervention whatsoever.

The Project Owner has made available a Water Quality Monitoring Program, with specifications for application during both the construction and operations phases. This program espouses a commitment to verify the effectiveness of environmental control measures designed to minimize the effects of works construction activities during the construction phase.

For further information on the Monitoring Program, see **Sections 8.2 and 8.3** in **Chapter 8 of the EIS**.

Remark N° 15

4. Ecological Flow Rates and Baseline Studies

The Project establishes an ecological flow rate for the Colorado River at 0.6 m³/s. This flow rate is outside of the bounds stipulated in the DGA Manual of Regulations and Procedures, which specifies that the value must be 10% of average annual flow rate - in this case, 3.1 m³/s plus environmental demand.

Our studies indicate that downstream of the intakes, the Yeso River dries out, the La Engorda Stream dries out, the Colina Stream dries out, the Las Placas Stream dries out, the Morado Stream dries out, and the Colorado River is left with a minimal flow rate. The ecological flow rates defined at the exits of the intakes will soak into the ground and not flow along the watercourses in question to their points of confluence with more major rivers, leaving them dry.

Ecological flow rates are determined based on the Environment Law, Law 19,300 and respecting the rights of third parties.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4 in Chapter 2 of the EIS**.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17 of the Addendum**.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to

intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams. It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of flow rates and water levels**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Q_e) approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
	Alto Volcán		
	Rain gauge station		
	406,157		
	Stream gauge station		
	6,259,100		
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 16

5. Impact on Sediments and Aggregates

The Project documentation itself states, in Annex 20, that potential aggregates production in the river basin will decline by around 3 million tons per year, which equates to more than 22% of total. This will affect the infrastructure of intakes, bridges, and water abstraction works, as well as the specific activity of aggregates extraction. If the authority has imposed a freeze on aggregates extraction permits in the first section of the Maipo River, how can it grant permission for a project that will extract 22% of all aggregates produced in the river basin?

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

riders and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum.**

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (**AGU.06.01**), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence. Watercourse degradation problems and effects on certain

highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted..

It can be concluded that the Maipo River system can be managed such that, With the Project operational , present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river.

In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in

flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level.

It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be identical to those currently observed.

It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times of the year flow rate in the Maipo River watercourse drops significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake owned by Aguas Andinas, etc.

Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual abstraction rate at these intakes varies between 78 and 164 m³/second.

This situation clearly explains the high level of perturbation observed in the behavior of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years.

It is for this reason that the Project Owner asserts that its activities will have no impact on the current situation in the sand extraction sites located on the Maipo River.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. The study also investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 17

5. Real Available Water Resources

Baseline studies to define ecological flow rates, taking into account the geology, local soil studies, and impact on flora and fauna, would certainly arrive at much lower figures for real available water resources than those presented. How much energy will this project really be able to generate?

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.03.01 Water resources

The baseline studies used in determining existing water resources in the Project area are presented in **Chapter 5.3.5 of the EIS**.

This section presents information characterizing the basins and tributaries of the Volcán, Yeso, and Colorado Rivers, all in the context of the Maipo River Mountain Hydrological System. This characterization describes the current situation of the aspects that are of relevance in the environmental evaluation, and in particular the features related to flow dynamics and the usage of water resources.

A number of sources have been used in the preparation of this characterization: various environmental studies belonging to the Directorate-General of Water (DGA), Meteorological Department of Chile, and Aguas Andinas, as well as the Water Resource Analysis reports conducted by Gener, which are attached in Annex

13 of Addendum 1; this information was used to determine the monthly average flow rates for each of the rivers and streams involved in the Project.

For more in-depth information on water resource baseline information, see **Annexes 13 and 17 of the Addendum, and Section 5.7.1.3 of the EIS**.

AGU.03.02 Geology

The baseline studies used in determining the geological characteristics of the Project area are presented in **Section 5.3.6 of the EIS**. Additionally, the **hydro-geological baseline studies** for the Project area are presented in **Section 5.3.5.3 of the EIS**. Complementary information is also provided in **Annex 45 of the EIS**.

Both of these studies start with general background information on the area where the Project is to be installed, going on to present a detailed description of the geological and geomorphological characteristics of specific areas where Project works or activities are planned.

Complementary information is provided in **Annex 8 of the Addendum**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to

intervention by means of a systematic characterization of the watercourses,

centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles,

70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3, and Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempeo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neoporteria curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Lilolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result,

populations of organisms consist mainly of introduced species (EIS 5.4.3).. For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

Remark N° 18

7. Impact on aquatic flora and fauna

The Project fails to identify the species that shall be affected by flow reductions in the El Volcán area sub-basin, and similarly fails to identify the conservation status and water and water-flow requirements of species identified.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.03.01 Water resources

The baseline studies used in determining existing water resources in the Project area are presented in **Chapter 5.3.5 of the EIS**.

This section presents information characterizing the basins and tributaries of the Volcán, Yeso, and Colorado Rivers, all in the context of the Maipo River Mountain Hydrological System. This characterization describes the current situation of the aspects that are of relevance in the environmental evaluation, and in particular the features related to flow dynamics and the usage of water resources.

A number of sources have been used in the preparation of this characterization: various environmental studies belonging to the Directorate-General of Water (DGA), Meteorological Department of Chile, and Aguas Andinas, as well as the Water Resource Analysis reports conducted by Gener, which are attached in Annex

13 of Addendum 1; this information was used to determine the monthly average flow rates for each of the rivers and streams involved in the Project.

For more in-depth information on water resource baseline information, see **Annexes 13 and 17 of the Addendum, and Section 5.7.1.3 of the EIS**.

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles,

70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3, and Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed

frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of

installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neopterteria curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo Spinolosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Lilolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

Remark N° 19

8. Impacts on Meadows and Wetlands

The Project does not mention impacts that it will incur through the reduction of flow rates in water bodies, in high altitude wetlands and meadows located within the Project's area of influence. It should be borne in mind that as a consequence of the construction of the Alfalfal I Plant, which became operational in 1991, a number of meadows/wetlands dried out.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate

that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth,

flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

SUE Soil Impact

The baseline studies used in determining the soil characteristics of the Project area are presented in **Section 5.3.4 of the EIS**. Complementary information is provided in **response 32 xiii in Section 5 of Addendum 1**. In general, the District of San José de Maipo features low soil quality, as a result of its topographic and geomorphological characteristics. According to a study conducted by the Instituto de Investigaciones de Recursos Naturales (IREN) (Pérez, W.; Tamayo, A.: 1996), most soils in the District are classified as dryland non-arable soils.

In the land areas that form the Project's area of influence, and in particular in the upper reaches of the Yeso River and Volcán River sub-basins and in the middle reaches of the Colorado River, current usage patterns are strongly influenced by relief characteristics and conditions, and prevailing high mountain climate conditions, which bring about a number of limiting factors - including physical factors and accessibility factors - affecting the development of human activities.

SUE.02 Soils, meadows, and wetlands

The Project Owner has conducted a number of studies with the aim of characterizing the vegetation of summer grazing areas (La Engorda) (see details in Addendum 1, Annex 6, and in Chapter 5 of the EIS), as well as flora and vegetation studies in the Project's area of influence (EIS, Chapter 5).

These studies contain information compiled in fieldwork campaigns conducted in Fall 2005, Spring 2006, November 2007, March 15 and 16, 2008, and September 2008, which add to the body of knowledge available regarding vegetation in these areas.

The Lo Encañado area shall be assigned a status of controlled access area for works contractors at all times: it shall not be subject to any intervention whatsoever. For more information on vegetation areas that could be affected by the construction works, and to learn about mitigation measures proposed by the Project Owner, you are advised to review Annex 42 of the EIS and Annex 6 of the Addendum.

With regard to environmental regulations that apply specifically to vegetation and plant life, the Project Owner shall be subject to:

Supreme Decree 366 (Exploitation of Tamarugo, Carob, Chañar, Guayacán, Aextoxicon, Charcoal, Acacia, Boldo, Maiten, Litre, Bollen, and Quillay). This legal instrument governs the felling of trees and bushes.

Supreme Decree 4363 and D.L 701 (Approving the Definitive Text of the Law on Woodland and Regulations on Forest Promotion).

Article 2 of the Woodland Law establishes an obligation that land classified as for preferential woodland land use, as well as natural and artificial woodlands, are subject to woodland management plans approved by the National Forestry Commission (CONAF). Furthermore, Article 21 of Decree Law 701 establishes that any felling or usage of native woodland shall be subject to the CONAF's prior approval of the corresponding management plan.

Decree 82 (Prohibiting the Felling of Trees and Bushes in Indicated Andean High Mountain and Foothill Areas)

Article 102 Sector Environmental Permit (Permit for the felling or exploitation of native woodland, in any type of land, or plantations located in land with preferential characteristics for woodland use).

For further information and analysis on the aforementioned regulations and permits, as applicable to the Project, as well as in terms of general aspects, compliance, and regulatory bodies, please see Sections 3.2.6 and 3.3.7 in Chapter 3 of the EIS.

Remark N° 20

9. Sustainability in the Maipo River Basin

The Company does not hold the corresponding water rights, and the Baseline studies are therefore not valid.

The Project does not comply with the Environmental Impact Assessment System. The company does not recognize the impacts that shall arise as a result of the extraction of water resources.

The Project is not capable of generating 530 MW. Data studied indicate that the company does not possess the water resources necessary to operate the Project, and does not hold corresponding water rights.

The Gener PHAM Project is not compatible with the sustainability of the Maipo River Basin.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively.

Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 of the year 1990, with Registry Number 202 in the Public Registry of Water Usage Rights (available for examination in **Section V, Question 24, Section vi of the Addendum**).

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work.

For more information, see **Annex 17** of the **Addendum**.

AGU.03.01 Water resources

existing in the Project area.

This section presents information characterizing the basins and tributaries of the Volcán, Yeso, and Colorado Rivers, all in the context of the Maipo River Mountain Hydrological System. This characterization describes the current situation of the aspects that are of relevance in the environmental evaluation, and in particular the features related to flow dynamics and the usage of water resources.

A number of sources have been used in the preparation of this characterization: various environmental studies belonging to the Directorate-General of Water (DGA), Meteorological Department of Chile, and Aguas Andinas, as well as the Water Resource Analysis reports conducted by Gener, which are attached in Annex

13 of Addendum 1; this information was used to determine the monthly average flow rates for each of the rivers and streams involved in the Project.

For more in-depth information on water resource baseline information, see **Annexes 13 and 17 of the Addendum, and Section 5.7.1.3 of the EIS.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not

commonly frequented, minimizing their visual impact.

Remark N° 21 Cultural Heritage

The Project shall affect sites of incalculable heritage value, and yet information is provided on only some of these sites, identified in the Baseline. Three areas are identified as featuring resources of cultural interest: Las Morrenas and Camino del Inka in the Lo Encañado Lake area, and the site known as Aucayes 1 in the Colorado River - Aucayes Stream area, as well as a site of paleontological interest as Alto Volcán.

What guarantees does the Project Owner provide to ensure that contractor companies respect this archeological and paleontological heritage? How many professionals will be tasked with providing training or monitoring of contractor companies? What legally-backed institution will monitor works and determine the significance of sites and remains discovered?

What institution will provide oversight in order to ensure legal minimal compliance? Contractual requirements affecting contractor companies are not sufficient.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

AGU.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum 1**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

Remark N° 22 Definition of Baseline 1

Where plans call for the construction of roads, intakes, muck disposal heaps, temporary encampments, and other such sites, the company fails to recognize the existence of a site of immense paleontological value that is unique in Chile: 150 million year old dinosaur footprints. Under the protection granted under current legislation, this area should be protected and no commercial project that would affect it should be conducted. No information is available on such ichnofossils of this age in Chile, so studying them could yield a major contribution to Chilean and global paleontology. Law 17,288 Title I - Art. I and Title III Art. 10-12-13.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

AGU.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum 1**.

ARQ.02 Values preservation

General paleontological protection measures:

i) **Restricted area applicable to contractor company employees**

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) **Delimitation of buffer zones**

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) **Contingency measures**

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) **Compensation measures**

- production of cultural information material**
- creation of a viewpoint**
- fossil trail**

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be

implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

Remark N° 23 Definition of Baseline 2

The Project documentation omits information on the existence of geological structures that are unique in Chile and that are of incalculable value, which currently constitute an "open air museum" and that could be subject to irreparable damage through the construction of the PHAM. These formations include a number of types of mudcrack and raindrop structures with ages between 155 and 150 million years. A detailed survey should be conducted to document these features, and the area should then be given protected status due to the scientific value of these structures, which are unique in Chile.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

AGU.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum**.

ARQ.02 Values preservation

General paleontological protection measures:

i) **Restricted area applicable to contractor company employees**

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) **Delimitation of buffer zones**

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) **Contingency measures**

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) **Compensation measures**

- a) **production of cultural information material**
- b) **creation of a viewpoint**
- c) **fossil trail**

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

ARQ.03 Scientific research

The scientific and cultural importance of the paleontological resources present has been recognized by the PHAM Project Owner, leading to a practice of taking particular care in selecting locations of works sites and installations in the Alto Volcán area, so as to protect and prevent the deterioration of all recorded or known resources. At the same time, the Project Owner has taken on a commitment to enhance knowledge of the area before starting planned works, undertaking survey studies of the Alto Volcán area, in parallel with suitable protection for sites recorded in that zone, as well as any new finds that may be detected during the course of construction under the PHAM. These activities will contribute not only to the

maintenance of the aforementioned resources, but shall also add to the recognition of the sites where they are found.

Thus, in the framework of procedures for the approval of the EIS, all available information on the most significant earth science materials and components has been compiled, as applicable to the PHAM area and surroundings, forming part of the country's non-renewable scientific/cultural heritage. Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of materials or components present.

For more information, see **Annex 14** of **Addendum 1**.

Remark N° 24
Cultural Heritage
Regarding Law 17,288

The law establishes that FOSSILS AND THE SITES WHERE THEY ARE LOCATED ARE A NATIONAL MONUMENT without specifying differences between paleontological pieces depending on their importance to science. In this regard, there is a need to identify how criteria will be established for the classification of pieces according to their scientific significance, the institutions or persons who shall act as guarantors, and the legal backing for conducting surveys of the quality described - as these are actions that infringe legislations in force. Law 17,288 Title V Art. 21-22-23.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. Thus, in the framework of procedures for the approval of the EIS, all available information on the most significant earth science materials and components has been compiled, as applicable to the PHAM area and surroundings, forming part of the country's non-renewable scientific/cultural heritage. Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of materials or components present.

For more information, see **Annex 14 of Addendum 1**.

Remark N° 25

Measures for the Protection or Preservation of Paleontological Heritage Existing in the Project's Area of Influence

Interventions at fossil sites implies the loss of material that no **known mitigation measure can resolve**. The extraction of a part of the material that is visible causes the loss of many other parts that remain covered. The removal of pieces and their deposition in other areas takes them out of their original context and leaves them stripped of all scientific value. In this regard, the Project Owner must specify what measures it shall implement if it does not possess permits issued by the National Monuments Council, for how long it shall support these measures, and what institution(s) will vouch for them.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

ARQ.03 Scientific research

The scientific and cultural importance of the paleontological resources present has been recognized by the PHAM Project Owner, leading to a practice of taking particular care in selecting locations of works sites and installations in the Alto Volcán area, so as to protect and prevent the deterioration of all recorded or known resources. At the same time, the Project Owner has taken on a commitment to enhance knowledge of the area before starting planned works, undertaking survey studies of the Alto Volcán area, in parallel with suitable protection for sites recorded in that zone, as well as any new finds that may

be detected during the course of construction under the PHAM. These activities will contribute not only to the maintenance of the aforementioned resources, but shall also add to the recognition of the sites where they are found.

Thus, in the framework of procedures for the approval of the EIS, all available information on the most significant earth science materials and components has been compiled, as applicable to the PHAM area and surroundings, forming part of the country's non-renewable scientific/cultural heritage. Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of materials or components present.

For more information, see **Annex 14** of **Addendum 1**.

Remark N° 26 Water Rights

The Project does not hold concessions for water rights at any abstraction point. A technical report exists, issued by the DGA, that concludes that it would not be possible to make available the water rights requested by Gener because there is no physical availability of water. How can a project of this nature be evaluated if it does not hold the required water rights? Will the Project attempt to take over water rights held by third parties?

Furthermore, a vast number of complaints have been lodged opposing these transfers of rights, in the Upper Maipo area and in the Colorado River, by private individuals, neighborhood groups, irrigation channel user associations, and the company Aguas Andinas.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively.

Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 of the year 1990, with Registry Number 202 in the Public Registry of Water Usage Rights (available for examination in **Section V, Question 24, Section vi of the Addendum**).

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in **Chapter 2 of the EIS.**

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

Remark N° 27 Baseline Study

Given that the project does not hold the water rights that it hopes to use, and that should such rights be granted, the flow rates conceded are as yet unknown, the baseline study is not valid because it is based on suppositions regarding flow rates.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively.

Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 of the year 1990, with Registry Number 202 in the Public Registry of Water Usage Rights (available for examination in **Section V, Question 24, Section vi of the Addendum**).

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.03.01 Water resources

The baseline studies used in determining existing water resources in the Project area are presented in **Chapter 5.3.5 of the EIS**.

This section presents information characterizing the basins and tributaries of the Volcán, Yeso, and Colorado Rivers, all in the context of the Maipo River Mountain Hydrological System. This

characterization describes the current situation of the aspects that are of relevance in the environmental evaluation, and in particular the features related to flow dynamics and the usage of water resources.

A number of sources have been used in the preparation of this characterization: various environmental studies belonging to the Directorate-General of Water (DGA), Meteorological Department of Chile, and Aguas Andinas, as well as the Water Resource Analysis reports conducted by Gener, which are attached in Annex 13 of Addendum 1; this information was used to determine the monthly average flow rates for each of the rivers and streams involved in the Project.

For more in-depth information on water resource baseline information, see **Annexes 13 and 17 of the Addendum, and Section 5.7.1.3 of the EIS.**

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

Remark N° 28 Ecological Flow Rates and Baseline Studies

The Project establishes an ecological flow rate for the Colorado River at 0.6 m³/s. This flow rate is outside of the bounds stipulated in the DGA Manual of Regulations and Procedures, which specifies that the value must be 10% of average annual flow rate - in this case, 3.1 m³/s plus environmental demand.

Our studies indicate that downstream of the intakes, the Yeso River dries out, the La Engorda Stream dries out, the Colina Stream dries out, the Las Placas Stream dries out, the Morado Stream dries out, and the Colorado River is left with a minimal flow rate. The ecological flow rates defined at the exits of the intakes will soak into the ground and not flow along the watercourses in question to their points of confluence with more major rivers, leaving them dry.

Ecological flow rates are determined based on the Environment Law, Law 19,300 and respecting the rights of third parties.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4 in Chapter 2 of the EIS**.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17 of the Addendum**.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to

intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams. It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

AGU.04.04 Monitoring and control of flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Q_e) approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
	Alto Volcán		
	Stream gauge station		
	406,157	6,259,100	
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 29

Impact on Sediments and Aggregates

The Project documentation itself states, in Annex 20, that potential aggregates production in the river basin will decline by around 3 million tons per year, which equates to more than 22% of total. This will affect the infrastructure of intakes, bridges, and water abstraction works, as well as the specific activity of aggregates extraction. If the authority has imposed a freeze on aggregates extraction permits in the first section of the Maipo River, how can it grant permission for a project that will extract 22% of all aggregates produced in the river basin?

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (**AGU.06.01**), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence. Watercourse degradation problems and effects on certain

highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted..

It can be concluded that the Maipo River system can be managed such that, With the Project operational , present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river.

In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in

flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level.

It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be identical to those currently observed.

It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times of the year flow rate in the Maipo River watercourse drops significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake owned by Aguas Andinas, etc.

Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual abstraction rate at these intakes varies between 78 and 164 m³/second.

This situation clearly explains the high level of perturbation observed in the behavior of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years.

It is for this reason that the Project Owner asserts that its activities will have no impact on the current situation in the sand extraction sites located on the Maipo River.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. The study also investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 30 Climate Change

The PHAM does not recognize or mention climate change or global warming. It is known that temperatures will rise, precipitation will diminish, and sea levels will rise. The Project Owner should take these variables into account in its study.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.04 Monitoring and control of flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Q_e) approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum.**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
Alto Volcán	Stream gauge station	406,157	6,259,100
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán)		
Alto Volcán	Control Station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control Station	406,780	6,260,782

Alto Volcán	Las Placas Intake Control Station Colina Intake	407,181	6,260,081
Alto Volcán	Control Station El Morado Intake	405,768	6,261,231

Remarks and Responses

Remark N° 30 Page 2

Yeso River	Rain gauge station PBN (15)	391,504	6,262,449
Yeso River	Control Station El Yeso Intake	399,666	6,272,077
Colorado River	Stream gauge station El Sauce	380,449	6,287,261
Colorado River	Intake control station Colorado River	389,063	6,292,501

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 31
Cultural, Paleontological, and Natural
Heritage:
1.- Baseline

In point V.6 in the EIS, regarding cultural heritage, the existence of heritage resources within the Project's area of influence is recognized, stating that "three areas are identified as featuring resources of cultural interest: Las Morrenas and Camino del Inca in the Lo Encañado Lake area, and the site known as Aucayes I in the Colorado River - Aucayes Stream area (...). In the Alto Volcán area, sites have been detected that may contain very ancient fossils or paleontological material (...) PHAM works shall not generate any direct intervention".

Further on in the document, in Table 7 (Identification, prediction, and evaluation of environmental impacts and risk situations) it is recognized that the Project shall have a LOW-SIGNIFICANCE NEGATIVE IMPACT on these resources. It should be pointed out that the impact on heritage resources is NEGATIVE AND IRREVERSIBLE (implying their destruction) and therefore cannot be considered to be of low significance.

Furthermore, in TABLE 6, it is stated the Project SHALL NOT AFFECT CULTURAL HERITAGE SITES IDENTIFIED IN THE BASELINE.

Please clarify the contradictions between information provided by the Project Owner in the baseline and in tables 6 and 7: Will the Project have an impact on the area's archeological and paleontological resources, or will it not?.

Please indicate why no information was provided on the Inca site at Laguna del Indio. This site is located just a few meters from the Inca trail located 1.5 km from the Project, and consists of a collection of structures in a natural depression, immediately to the W of the Laguna del Indio (Yeso River). The site contains four main enclosures, separated by a central passageway, with each enclosure subdivided into smaller rooms. Several of these rooms show clear evidence of looting. (UTM 396,500 E 6,274,479 N) Elevation 2692 m. The site features a number of architectural features typical of Inca architecture (Late period, c. 1470 to 1535 CE). The site features typical construction techniques, with double walls filled in with small stones. The central passage features a precise E-W orientation, and the layout divides the site perfectly into four parts. The site is associated with the Inca Trail known as the Camino del Inca (see the publication *Nuevos Registros de Asentamiento Inca en la cordillera andina de Chile Central*. Luís E. Cornejo B., Miguel A. Saavedra v. & Héctor Vera C. 2006.).

Please clarify why no reference is made to the existence of published sites located near to the Project.

Thematic responses

ARQ Archeological and
Paleontological Sites:
Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

AGU.01
Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum**.

1.
ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest

(e.g. concentrations of

Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

ARQ.03 Scientific research

The scientific and cultural importance of the paleontological resources present has been recognized by the PHAM Project Owner, leading to a practice of taking particular care in selecting locations of works sites and installations in the Alto Volcán area, so as to protect and prevent the deterioration of all recorded or known resources. At the same time, the Project Owner has taken on a commitment to enhance knowledge of the area before starting planned works, undertaking survey studies of the Alto Volcán area, in parallel with suitable protection for sites recorded in that zone, as well as any new finds that may be detected during the course of construction under the PHAM. These activities will contribute not only to the maintenance of the aforementioned resources, but shall also add to the recognition of the sites where they are found.

Thus, in the framework of procedures for the approval of the EIS, all available information on the most significant earth science materials and components has been compiled, as applicable to the PHAM area and surroundings, forming part of the country's non-renewable scientific/cultural heritage. Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of materials or components present.

For more information, see **Annex 14 of Addendum 1**.

Remark N° 32
Cultural, Paleontological, and Natural
Heritage:
2.- Environmental Monitoring Plan

Chapter 8 contains the Environmental Monitoring Plan, which will allow the monitoring of relevant environmental variables that have given rise to the content of the EIS. Here, the Project Owner states that *"The PHAM hereby submits to the SEIA that during execution of the Project certain effects, characteristics, or circumstances referred to in subsections b), d), e), and f) of Article 11 of Law 19,300 may arise or be caused, and that therefore the implementation of the Project shall include a suite of mitigation, compensation, or restoration measures that are suitable for offsetting these effects"*. Part f) of that Article refers to *"alteration of monuments, sites with anthropological, archeological, or historic value, and, in general, sites belonging to cultural heritage"*, including areas of paleontological interest.

Although heritage is specifically recognized as a relevant environmental variable, it is recognized that it will be affected by a negative impact, and the presence of a suitable professional is proposed, in order to undertake continual monitoring during the construction phase; nonetheless, the EIS does not contain plans to integrate this action into the environmental monitoring plan.

Clarify these contradictions.

Thematic responses

ARQ Archeological and
Paleontological Sites:
Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of materials or components present.

For more information, see **Annex 14 of Addendum 1**.

Remark N° 33
Cultural, Paleontological, and Natural
Heritage:
3. Preventive measures

In order to protect heritage resources, the Project Owner plans to obtain "continual on-site expert advisory services to prevent or minimize impact" (table 7). At which work sites will archeological monitoring be implemented? This question should also be taken to include muck disposal sites, sites for the extraction of aggregates and sand, and works involving improving, widening, and maintaining roads.

Furthermore, we do not consider this measure to constitute a "risk and accident prevention measure", but that it should rather be included in the environmental monitoring plan, for the reasons expressed in the previous point.

Thematic responses

ARQ Archeological and
Paleontological Sites:
Heritage

Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of materials or components present.

For more information, see **Annex 14** of **Addendum 1**.

Remark N° 34
Cultural, Paleontological, and Natural
Heritage:
4. Sites of Paleontological Interest

The Project Owner plans to conduct a complementary paleontological study in advance of construction, and to implement certain management measures to protect the resources currently registered with the SPACH, and other resources that may be discovered. In this regard, during the evaluation of the first EIS presented, which is currently under review, the CMN, which is the competent body in the field, has already issued a request for the preparation of a report that has yet to be produced.

When does the Project Owner plan to comply with this requirement? Specifically, what are the “management measures” that the Project Owner plans to implement to protect these resources?.

Thematic responses

on a commitment to enhance knowledge of the area before starting

planned works, undertaking survey studies of the Alto Volcán area, in parallel with suitable protection for sites recorded in that zone, as well as any new finds that may be detected during the course of construction under the PHAM. These activities will contribute not only to the maintenance of the aforementioned resources, but shall also add to the recognition of the sites where they are found.

Thus, in the framework of procedures for the approval of the EIS, all available information on the most significant earth science materials and components has been compiled, as applicable to the PHAM area and surroundings, forming part of the country's non-renewable scientific/cultural heritage. Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of materials or components present.

For more information, see **Annex 14** of **Addendum 1**.

Remark N° 35
Cultural, Paleontological, and Natural
Heritage:
5. Annex 43

This annex contains the minutes of a meeting held on January 3, 2008, and it is therefore not appropriate to cite it in the Project assessment currently under review. Furthermore, it is there stated that the issue of paleontological heritage is outside of the remit of the PAC and ICSARA (we assume that this refers to the EIS that was withdrawn), and yet the Project Owner states that "AES Gener thanks the SPACH for highlighting the scientific and cultural value of these bodies of evidence, which it recognizes and respects, and although they do not fall within the established procedure it shall include them as part of the citizen participation process". As stated in point 4 of this document, the CMN (the applicable competent body) has yet to issue a statement on the significance of these paleontological resources, and requested the preparation of a report complying with the items specified in the corresponding ordinance. The Project Owner has yet to respond to this requirement. Additionally, the minutes contained in Annex 43 also set forth a series of items agreed with the SPACH, including: "Based on these concepts, within the next two days the SPACH shall prepare a methodological proposal to form an agreement with AES Gener regarding the scope, by means of a joint agreement that includes the commitments made in the agenda." If this proposal must be submitted by January 5, why was it not included in the study currently under review? The following item states that: "All necessary permits shall be submitted for procedures conducted by the SPACH, and this body shall be directly involved in the procedures to be implemented." In this regard, the Project Owner is requested to indicate the name of the qualified paleontologist who shall be responsible for obtaining these permits.

The Project Owner is hereby informed that the permits granted by the CMN for intervention in this type of resource are personal in nature, and therefore cannot be requested by the SPACH. Requests made to the CMN must specify a number of points, including the professional responsible for the activity, work team, specialists who are to analyze materials, and methodology for excavation or recovery of finds, and analysis (see the regulations on Law 17,288, on persons authorized to conduct surveys and request permits to excavate and intervene affecting such resources). Finally, the Project Owner is hereby informed that excavation permits constitute a sector environmental permit, and as this permit is necessary, it should already be requested under the study presented in the plan for compliance with environmental legislation in force (Point 2 of the executive summary)

Thematic responses

ARQ Archeological and
Paleontological Sites:
Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

AGU.01
Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental

damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access

restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) **production of cultural information material**
- b) **creation of a viewpoint**
- c) **fossil trail**

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

Remark N° 36
Cultural, Paleontological, and Natural
Heritage:
6. The El Morado
Monument

CONAF, in Ordinance 30 dated February 5, 2008, and Ordinance 70 dated April 9, 2008, requested that the line taken by the tunnel be adjusted so as not to enter this protected area, as it considered that the Project Owner had been unable to guarantee that the construction and operation of the El Volcán Tunnel would not lead to impacts on the resources and processes that the area protects - in particular, geological and geomorphological processes and features, including the glacier and fossil-bearing strata; rather, the Project Owner was only able to express that the occurrence of problems or contingencies was of low likelihood.

The objective of the creation of this monument was "To preserve an ecosystem that is representative of the Upper Maipo Basin (Morales Stream) through the protection of its natural scenic beauty, its geological and geomorphological processes, and its endangered life-forms". The area's specific conservation objectives include "preservation of the geological and geomorphological processes and features present in the Area, including the glacier and fossil-bearing strata; protection of the Area's natural scenic beauty, including its glacier, vegetation, lake, streams, mineral waters, and fossil-bearing rock strata, and support of scientific research into its natural and cultural resources, permitting the enhancement of knowledge regarding the area".

Clarify these contradictions, and explain why the modification requested have not been implemented.

Thematic responses

ARQ Archeological and
Paleontological Sites:
Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

AGU.01
Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum 1**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compe neasures

- a) a)production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

ARQ.03 Scientific research

The scientific and cultural importance of the paleontological resources present has been recognized by the PHAM Project Owner, leading to a practice of taking particular care in selecting locations of works sites and installations in the Alto Volcán area, so as to protect and prevent the deterioration of all recorded or known resources. At the same time, the Project Owner has taken on a commitment to enhance knowledge of the area before starting planned works, undertaking survey studies of the Alto Volcán area, in parallel with suitable protection for sites recorded in that zone, as well as any new finds that may be detected during the course of construction under the PHAM. These activities will contribute not only to the maintenance of the aforementioned resources, but shall also add to the recognition of the sites where they are found.

Thus, in the framework of procedures for the approval of the EIS, all available information on the most significant earth science materials and components has been compiled, as applicable to the PHAM area and surroundings, forming part of the country's non-renewable scientific/cultural heritage. Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of materials or components present.

For more information, see **Annex 14 of Addendum 1**.

Remark N° 37
Cultural, Paleontological, and Natural
Heritage:
7. Protected areas: La Engorda
Meadow

The EIS contains plans to alter these meadows/wetlands through installing pipelines running underneath them, construction of inlets, and construction of certain access routes and the El Morado siphon. In this regard, it can be stated that - as is suggested by its name - this meadow and the vegetation that surrounds it represent a unique ecosystem, which is of particular importance due to its use fattening up livestock. Nonetheless, the Project does not feature suitable mitigation and compensation measures.

The Project Owner should include the mitigation and compensation measures that it therefore plans to implement.

Thematic responses

F&F Biodiversity Impact

Flora and
Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles,

70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of
species affected

Aquatic flora and
fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3, and Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and
vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neoporteria curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial
fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Lilolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and
fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic

communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

F&F.02.02 Mitigation

Aquatic flora and fauna

The Project calls for a suite of multi-purpose environmental management measures that aim to minimize its effects on living organisms, including: minimization of watercourse areas to be subject to intervention by prioritizing such works for late summer and early fall seasons (period of lowest flow rates), the adoption of special precautions to prevent accidental spillages into watercourses (prohibition of the storage of lubricant drums in or near watercourses, etc), and permanent maintenance of ecological flow rates.

For more detailed information, including technical documentation that complements the information described above, see Annex 17 of the Addendum.

Terrestrial Flora and Vegetation

In order to prevent and/or minimize the Project's effects on plant life, it plans to adopt a number of integrative measures: micro-routing in advance of starting work on-site, in order to identify specimens of plants listed in any conservation category and subject to impact; compensation with the planting of 10 specimens for every one destroyed, in the case of non-woodland species listed for conservation; implementation of a woodland management plan applicable to woodland areas, which describes its measures in accordance with Article 5 of the Woodland Law; implementation of vegetation restoration plans at muck disposal sites, encampments, artificial slopes, and tunnel access terraces (EIS, Annexes 7 and 29). More in-depth information on complementary measures is provided in Annex 6 of Addendum 1.

Terrestrial fauna

Specific wildlife environmental management measures have been proposed for each particular species, taking into account prior experience in the success of these measures in similar projects. These measures will be implemented in continual coordination with the Servicio Agrícola y Ganadero. Principal measures include: capture of individuals belonging to species of conservation interest for rescue and relocation; controlled perturbation actions; and habitat replacement. Other measures are based on the use of signage, training for Contractors, and contractual requirements for on-site supervision (see details in Section 6.4.1.6 of the EIS).

See Annex 4 of the Addendum for the native wildlife rescue and relocation plan.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as

making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

SUE Soil Impact

The baseline studies used in determining the soil characteristics of the Project area are presented in **Section 5.3.4 of the EIS**. Complementary information is provided in **response 32 xiii in Section 5 of Addendum 1**. In general, the District of San José de Maipo features low soil quality, as a result of its topographic and geomorphological characteristics. According to a study conducted by the Instituto de Investigaciones de Recursos Naturales (IREN) (Pérez, W.; Tamayo, A.: 1996), most soils in the District are classified as dryland non-arable soils.

In the land areas that form the Project's area of influence, and in particular in the upper reaches of the Yeso River and Volcán River sub-basins and in the middle reaches of the Colorado River, current usage patterns are strongly influenced by relief characteristics and conditions, and prevailing high mountain climate conditions, which bring about a number of limiting factors - including physical factors and accessibility factors - affecting the development of human activities.

SUE.01 Regulations

The Project Owner is subject to the following regulations, which are specified in detail in Chapter 5 of the EIS, Section 5.7.2.1, regarding the Santiago Metropolitan Master Plan.

With regard to planning instruments, the PHAM is to be implemented in the district of San José de Maipo, which does not have a District Master Plan (one is currently being prepared), and which only has current urban limits for the settlements of San Alfonso, La Obra, San José de Maipo, El Melocotón, San Gabriel, and Las Vertientes. Conversely, the Santiago Metropolitan Master Plan (PRMS) establishes a number of land use regulations that apply to the project area, most of which are related to ecological preservation and/or protection and risks. Most of the district's surface area is classed as Ecological Preservation Area, which aims to maintain a zone's natural state, in order to preserve and contribute to the environment's quality and equilibrium, as well as to preserve landscape heritage (see further information in the conclusions stemming from analysis of regulations, in Section 5.7.3, Chapter 5 of the EIS).

Supreme Decree 366 (Exploitation of Tamarugo, Carob, Chañar, Guayacán, Aextoxicon, Charcoal, Acacia, Boldo, Maiten, Litre, Bollen, and Quillay). This legal instrument governs the felling of trees and bushes.

Supreme Decree 4363 and D.L 701 (Approving the Definitive Text of the Law on Woodland and Regulations on Forest Promotion).

Article 2 of the Woodland Law establishes an obligation that land classified as for preferential woodland land use, as well as natural and artificial woodlands, are subject to woodland management plans approved by the National Forestry Commission (CONAF). Furthermore, Article 21 of Decree Law 701 establishes that any felling or usage of native woodland shall be subject to the CONAF's prior approval of the corresponding management plan.

Decree 82 (Prohibiting the Felling of Trees and Bushes in Indicated Andean High Mountain and Foothill Areas)

Article 102 Sector Environmental Permit (Permit for the felling or exploitation of native woodland, in any type of land, or plantations located in land with preferential characteristics for woodland use).

For further information and analysis on the aforementioned regulations and permits, as applicable to the Project, as well as in terms of general aspects, compliance, and regulatory bodies, please see Sections 3.2.6 and 3.3.7 in Chapter 3 of the EIS.

SUE.02 Soils, meadows, and wetlands

The Project Owner has conducted a number of studies with the aim of characterizing the vegetation of summer grazing areas (La Engorda) (see details in Addendum 1, Annex 6, and in Chapter 5 of the EIS), as well as flora and vegetation studies in the Project's area of influence (EIS, Chapter 5).

These studies contain information compiled in fieldwork campaigns conducted in Fall 2005, Spring 2006, November 2007, March 15 and 16, 2008, and September 2008, which add to the body of knowledge available regarding vegetation in these areas.

The Lo Encañado area shall be assigned a status of controlled access area for works contractors at all times: it shall not be subject to any intervention whatsoever. For more information on vegetation areas that could be affected by the construction works, and to learn about mitigation measures proposed by the Project Owner, you are advised to review Annex 42 of the EIS and Annex 6 of the Addendum.

With regard to environmental regulations that apply specifically to vegetation and plant life, the Project Owner shall be subject to:

Supreme Decree 366 (Exploitation of Tamarugo, Carob, Chañar, Guayacán, Aextoxicon, Charcoal, Acacia, Boldo, Maiten, Litre, Bollen, and Quillay). This legal instrument governs the felling of trees and bushes.

Supreme Decree 4363 and D.L 701 (Approving the Definitive Text of the Law on Woodland and Regulations on Forest Promotion).

Article 2 of the Woodland Law establishes an obligation that land classified as for preferential woodland land use, as well as natural and artificial woodlands, are subject to woodland management plans approved by the National Forestry Commission (CONAF). Furthermore, Article 21 of Decree Law 701 establishes that any felling or usage of native woodland shall be subject to the CONAF's prior approval of the corresponding management plan.

Decree 82 (Prohibiting the Felling of Trees and Bushes in Indicated Andean High Mountain and Foothill Areas)

Article 102 Sector Environmental Permit (Permit for the felling or exploitation of native woodland, in any type of land, or plantations located in land with preferential characteristics for woodland use).

For further information and analysis on the aforementioned regulations and permits, as applicable to the Project, as well as in terms of general aspects, compliance, and regulatory bodies, please see Sections 3.2.6 and 3.3.7 in Chapter 3 of the EIS.

Remark N° 38

Effects of the presence of Run-of-the-River Hydroelectric Plants in the Maipo River Basin Regarding Renewal of Aggregates Resources

In accordance with Supreme Decree 95/01, Reglamento S.E.I.A.

Article 6: The Project generates significant adverse effects on the quality and quantity of renewable natural resources, including soil, water, and air.

THE PHAM'S EIS DOES NOT CONSIDER THE CORRECT MAGNITUDE OF IMPACTS ON NATURAL AGGREGATES RESOURCES in the Volcán, Colorado, Yeso, and Maipo Rivers.

According to the book *Industria del Árido en Chile – Sistematización de Antecedentes Técnicos Ambientales*, Volume I, Santiago, published in December 2001 by the Comisión Nacional de Áridos y Corporación de Desarrollo Tecnológico, with the support of the Ministry of Public Works, Ministry of Housing, and Chilean Chamber of Construction, aggregates resources are considered renewable if they are extracted from watercourses.

The run-of-the-river power plants that operate in the Upper Maipo Basin (Volcán Queltehues, Alfalfal, and Los Maitenes) have altered the natural dynamics of solids transport in the watercourses, particularly in the case of sands. This is due to the following facts:

- 1) Sand is trapped in sand traps, as it is damaging to headworks and turbines. If the water is returned to the watercourses, this does not occur in a timely manner; and the sections of watercourses between abstraction works and points of water return suffer a drop in solid transport capacity, as a result of the reduction in water flow rate;
- 2) Gravel trap flushing at intakes does not guarantee that sediments continue on downstream, as such events occur at low frequency - which factor, combined with the decline in flow rates, favors the consolidation of materials in the stretches between water abstraction and return;
- 3) The clean water returned into the watercourses causes erosion, does not contribute sediments, and generates an imbalance in aggregates resources (input without sediment and output with sediment implies erosion);
- 4) Persons engaged in artisanal sand production in San José de Maipo state that when the Alfalfal and Los Maitenes, located in the Colorado River sub-basin became operative, sand production in this sub-basin suffered a permanent decline of approximately 30%.

It should also be mentioned that, apart from the four sub-basins that form the Upper Maipo Basin (bounded by the Maipo River rain gauge station at El Manzano), at present only the El Volcán sub-basin is free of any intervention that could have a negative impact on sediment transport in the Upper Maipo River Basin.

It is considered necessary that the Project Owner should characterize the sediment transport dynamics of the Upper Maipo River Basin, as well as sources of production, and should evaluate levels of impact on sand transport, principally, associated with existing and planned power plants. This information should be included in the Environmental Impact Study baseline.

Furthermore, in order to evaluate the Project's impact on the sediment load from the Volcán River sub-basin, the Project Owner is required to include a complete hydrological study for this sub-basin, defined as the section of the Volcán River located immediately upstream of the point where it empties into the Maipo River.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study** presented in **Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap

particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses.

through periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (**AGU.06.01**), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted.

It can be concluded that the Maipo River system can be managed such that, With the Project operational, present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river.

In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in

flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level.

It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be identical to those currently observed.

It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times of the year flow rate in the Maipo River watercourse drops significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake owned by Aguas Andinas, etc.

Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual abstraction rate at these intakes varies between 78 and 164 m³/second.

This situation clearly explains the high level of perturbation observed in the behavior of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years.

It is for this reason that the Project Owner asserts that its activities will have no impact on the current situation in the sand extraction sites located on the Maipo River.

AGU.06.04 Discharge effects

Water capture in advance of in-situ gravel removal leads first to a reduction in sediment load in water carried through the headworks to the turbine rooms, while the solid materials that is retained is returned to the river. At the point where water is discharged from the plants (Las Lajas area), water that has passed through the turbines - which contains a certain quantity of sediment - once again mixes with the water in the rivers, returning to its original conditions in terms of

average sediment load (**Addendum, Section I, Question 28**).

At the point where water is returned to the Maipo River, in the Las Lajas area, there will be no degradation of the riverbed as it is composed entirely of rocks. It should be mentioned that the flow rate discharged from the PHAM at this

point is always lower than the flow rate in the Maipo River just upstream. During the operations phase of the Project, planned maintenance activities do not include any cleaning of tunnels and culverts. Inside the tunnels, the cross sectional area for water flow is small enough to prevent sedimentation. This is shown through the operation of the Alfalfal Plant for 20 years without any cleaning of the tunnels being included among maintenance activities.

The only operations that lead to the discharge of sediment are the discharge of gravel traps at the inlets, and the flushing of the sand traps, returning sediment to the river once a certain volume has built up within them. These operations are conducted intermittently and for short time periods (1 minute for sand traps, 10 minutes for gravel traps), at variable frequency depending on the season. For more information see the **Addendum, Section IV, Question 3.**

Remark N° 39

Erosion Impacts on the Maipo River Due to the Discharge of Clean Water and Hydrological Changes Due to Synergies Between Impacts

The Maipo River watercourse will suffer erosion downstream of the plants' spillways due to the effects of clean water, which carries no solids in suspension.

The water used in hydroelectric power generation are returned to the main course of the Maipo River between the El Canelo and El Manzano areas. In view of the operating capacity of these run-of-the-river power plants, which implies a potential discharge of 65 m³/s, is it cause for concern that no analysis has been conducted into the erosion effects of these altered flow dynamics downstream, which alter the natural drainage regime of the Upper Maipo River.

The Project Owner must evaluate the erosive effects of water returned to the system from the PHAM. The effect should be analyzed mainly for the months from October through March, during the ice melt season.

These negative effects are interlinked, as the lack of entry of solid materials downstream of the point of discharge results in imbalances that lead to changes in the Maipo River's hydrogeological system.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum.**

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study** presented in **Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfal Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total

solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential expected solid streambed wear/entrainment (transport capacity) in the rivers, calculated based on the theoretical modeling of their hydraulic characteristics

and theoretical numerical relationships.

2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (AGU.06.01), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted.

It can be concluded that the Maipo River system can be managed such that, With the Project operational, present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

Remark N° 40

Impacts on Aggregates Extraction Activities in the Districts of San José de Maipo, Puente Alto, Pirque, San Bernardo, and Buin

The PHAM's planned water intakes in the Volcán River sub-basin will lead to the following effects:

- 1) Given that the Project will inhibit practically all of the water flow provided by ice-melt attributable to the Volcán River sub-basin during the October - March ice melt season, only water from the Maipo River sub-basin will be available to transport sediment in a stretch approximately 60 km in length, running from the junction with the Volcán River and the Maipo River to the junction with the Colorado River and the Maipo River. It should be noted that the Yeso River is totally modified by the Laguna Negra and Lo Encañado reservoirs, such that its contribution to ice melt water flow is insignificant or nonexistent;
- 2) Considering that it is a fact that most renewal of small particle size material occurs during the ice melt season, it can be stated that in terms of the renewal of aggregates resources, the PHAM shall impact 75% of such resources in the Upper Maipo River Basin - an utterly foreseeable impact with undefined repercussions in view of the nature of the Project, and therefore impossible to rule out;
- 3) Water discharged from the PHAM shall exacerbate the sediment deficit downstream of the point of discharge;
- 4) In the districts of San José de Maipo, Puente Alto, Pirque, San Bernardo, and Buin, intensive aggregates extraction activities are undertaken. This activity already presents limitation that are the subject of studies to determine whether there is a need to partially restrict extractive activities, and whether an environmentally sustainable project running across these districts can be instituted, taking in the stretch of river from the outflow of the Clarillo River through to the Puntilla de Lonquén Railway Bridge.

Additionally the DOH, by way of Official Communication DOH RM N° 462 dated 24 May, 2006, has imposed a zone where extractive activities are restricted running four kilometers upstream and downstream of the Maipo Bridge (Pan-American Highway), only approving projects based on the natural renewal of the resource. As the Maipo River falls within the jurisdiction of these districts, and in view of the ex-ante presence of the PHAM, and the vulnerable nature of this activity, the importance of aggregates as a raw material for construction, and economic and social repercussions particularly affecting irrigation, it can be shown that the PHAM's area of direct influence should extend through to the Maipo River at the Puntilla de Lonquén Railway Bridge. Studies required: In response to the questions raised above, the PHAM is requested to conduct the following studies in order to verify effects on the Maipo River in the medium and long term:

- * Study on the loss of aggregates through retention in intakes
- * Study on the loss of aggregates through reduced solid transport capacity in river water
- * Study on erosion in the river system through the effects of discharging clean water
- * Study on changes in the hydro-geological system of the Maipo River Valley

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should

be expected to contain 85% of the sediment in

suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (**AGU.06.01**), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted.

It can be concluded that the Maipo River system can be managed such that, With the Project operational, present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river.

In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in

flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level.

It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be identical to those currently observed.

It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times of the year flow rate in the Maipo River watercourse drops significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake owned by Aguas Andinas, etc.

Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual abstraction rate at these intakes varies between 78 and 164 m³/second.

This situation clearly explains the high level of perturbation observed in the behavior of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years.

It is for this reason that the Project Owner asserts that its activities will have no impact on the current situation in the sand extraction sites located on the Maipo River.

AGU.06.04 Discharge effects

Water capture in advance of in-situ gravel removal leads first to a reduction in sediment load in water carried through the headworks to the turbine rooms, while the solid materials that is retained is returned to the river. At the point where water is discharged from the plants (Las Lajas area), water that has passed through the turbines - which contains a certain quantity of sediment - once again mixes with the water in the rivers, returning to its original conditions in terms of

average sediment load (**Addendum, Section I, Question 28**).
At the point where water is returned to the Maipo River, in the Las
Lajas area, there will be no degradation of the riverbed as it is composed entirely

of rocks. It should be mentioned that the flow rate discharged from the PHAM at this point is always lower than the flow rate in the Maipo River just upstream.

During the operations phase of the Project, planned maintenance activities do not include any cleaning of tunnels and culverts. Inside the tunnels, the cross sectional area for water flow is small enough to prevent sedimentation. This is shown through the operation of the Alfalfal Plant for 20 years without any cleaning of the tunnels being included among maintenance activities.

The only operations that lead to the discharge of sediment are the discharge of gravel traps at the inlets, and the flushing of the sand traps, returning sediment to the river once a certain volume has built up within them. These operations are conducted intermittently and for short time periods (1 minute for sand traps, 10 minutes for gravel traps), at variable frequency depending on the season. For more information see the **Addendum, Section IV, Question 3.**

Remark N° 41

Impacts on the Socio-Economic Structure Regarding Activities Conducted by Artisanal Sectors and Industries Engaged in the Extraction of Aggregates Throughout All Tributaries of the Maipo River

In accordance with Supreme Decree 95/01, S.E.I.A. Regulations:

Article 8: The Project causes the resettling of human communities or significant changes in the ways of life or customs of human groups.

THE PHAM'S EIS DOES NOT CONSIDER IMPACTS ON SOCIO-ECONOMIC ASPECTS regarding activities conducted by artisanal sectors and industries engaged in the extraction of aggregates throughout all tributaries of the Maipo River.

- * The limits established for the PHAM's area of influence are insufficient in terms of establishing socio-economic impacts, given that in these terms the Project's environmental impact affects extractive activities in all tributaries of the river system, that is, from San José de Maipo to Lonquén.
- * The absence of a study to evaluate the existence of this activity, as well as the impacts that shall be caused by the PHAM. The environmental impact study ignores the presence of this industry sector, which is of importance for the development of the region.

GROUNDING FOR THE TWO REMARKS

A little history: Since around the year 1900, the banks of the Maipo River have been the site of major production activity in the field of aggregates extraction. During the early years, this was an almost purely small-scale activity, undertaken by the families who lived along the riverbanks, who suffered greater harm with every year that passed through the flooding of what was a very different watercourse to the form that it currently takes.

As the decades passed, this activity became an industry not only for the families who lived along the river's banks; as the industry grew, and as demand for aggregates in the region rose, the sector saw major development leading to the start of a significant industrial activity, advancing side by side with artisanal sectors. This was such a major industry that areas like the Cajón del Maipo owed their development to this extractive industry.

Starting in the 1990s, and with the return of democracy, the small-scale producers who were the descendents of the first families to settle on the riverbank formed syndicates that still exist today. This was also the time when the boundaries of extraction areas were set. On request by the "Federación 22 de Enero", which is an association of sand production syndicates in the Maipo River, and by way of the Zoning Act of 1990, it was agreed that a systems of zones would be established limiting extraction activities, applying to both sand production syndicates and companies active in the industry.

An integral part of this agreement constituted an artisanal aggregates extraction program in this stretch of the river, as well as 5 annexes containing basic information on the extraction program for each of the syndicates that made up the "Federación 22 de Enero", base cartographic material specifying the zoning system, and technical guidelines for aggregates extraction (artisanal and mechanized). Under the river's 1990 zoning system, areas are set aside exclusively for artisanal activities, and, in view of the rapid development of mechanized activities, other areas were specified for associated artisanal/mechanized extraction (with industrial groups).

On the Syndicates

Along the stretch of the river running from the Los Morros Bridge to the Maipo Bridge, 7 syndicates have been identified, in addition to the syndicates located in Pirque, Puente Alto, and Lonquén, all of which specifically identify their key activity as aggregates extraction and which possess significant organizational capacity. All in all, there are approximately 1500 persons employed exclusively in aggregates extraction, as well as a significant number of truck owners, drivers, and resource location personnel. It is therefore estimated that around 4,500 persons in the region make their living from this activity (consisting of the family groups to which each industry worker belongs).

Additionally, these syndicates form an important resource in terms of social support for their members, as they take on the role of providing social resources and materials when any of their members falls ill, or becomes unable to continue to engage in their work as a result of invalidity or old age. Thus, for example, a proportion of the financial resources earned through aggregates production is set aside to ensure the survival of persons who are unable to continue to take part in the industry for these reasons, and their families. This provision is also guaranteed for the widows of syndicate members.

On the Companies

In addition to the syndicates, approximately 14 companies are engaged in aggregates extraction along the Maipo River, not including the major cement production companies that gather this resource from the river - which shall also be affected by the Project, and which are similarly not considered in the EIS.

From a cultural point of view, it is important to underscore that the trade of sand production is one that is passed down from generation to generation. Children of producers start to take part in the activity at a very early age, when their parents or grandparents pass on their knowledge to the next generation. In this regard, even a temporary interruption in studies represents a significant problem for this group of people. In view of the relevance of this consideration explained above, the question thus arises of the possibility of a change in trade activity in the event that a lack of aggregates renders this sector non-productive - given that, as some syndicate members put it, "a sand man is born and dies in the river", and the knowledge and skills of syndicate members are strongly or exclusively linked to aggregates extraction. Furthermore, and as indicated above, a large number of persons are not directly engaged in aggregates extraction, but do depend on this industry for their livelihood. In this regard, any impact on the activity also implies the creation of new social problems specifically associated with unemployment, together with the disappearance of an item of cultural heritage that has been a driving force behind development in the region.

Regarding the questions: Based on the above, and from a socio-economic perspective, two questions are presented to the PHAM:

- * How will the Project ensure the permanence and development of extractive industry in the Maipo River?
- * How will the Project guarantee to municipal/district governments that it will ensure the permanence of resources derived from extraction, if the extractive industry is affected?

Studies required: In response to the questions raised above, the PHAM is requested to conduct a study of the socio-economic impacts that will be caused by the operation of the

Proyecto Hidroeléctrico Alto Maipo, affecting artisanal and mechanized sand extraction industries that depend on the Maipo River, in the medium and long term.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediments

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**Chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river.

In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level.

It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be identical to those currently observed.

It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times of the year flow rate in the Maipo River watercourse drops significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake owned by Aguas Andinas, etc.

Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual abstraction rate at these intakes varies between 78 and 164 m³/second.

This situation clearly explains the high level of perturbation observed in the behavior of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years.

It is for this reason that the Project Owner asserts that its activities will have no impact on the current situation in the Sand extraction sites located on the Maipo River.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. The study also investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 42

Other Remarks

What is the contribution of the Volcán River sub-basin to total flow rates during the ice-melt season (October-March)?

What are the total contributions from ice-melt?

What is the effect on base flow rates in the rain precipitation and snow precipitation seasons?

What is the level of sediment input from the Volcán River sub-basin?

Why is it not deemed that all sediments from this sub-basin will be withdrawn, in view of its snow-driven flow dynamics?

How much sediment will be retained in high mountain intakes?

How much sand will be produced by the sand traps? Where will this material be disposed of?

Given that flow rates in the Volcán River sub-basin currently contribute not only to the snow melt flow of the Maipo River but also to the river's base flow rate, and given that the transport capacity will be modified in different sections of the river, how will the Project Owner manage this effect?

Sediment availability will decline not only through the inhibition of input from the Volcán River sub-basin, as well as through the erosive effect of the clean water discharged, but also because the transport capacity will be artificially increased in terms of magnitude and frequency. How will the Project Owner manage this effect?

In the EIS, the Project Owner indicates that it will construct a series of installations that shall have to be subcontracted, transferring the requirement for approval for the transport of aggregates from their point of extraction to the construction site; however, these works will be part of the Project. Clarification is required in this regard.

In the EIS, it is determined that the area of direct influence constitutes the district of San José de Maipo, as modifications to the hydro-geological dynamics of the river shall affect socio-economic issues that depend on aggregates resources (municipal government-run, industrial, and artisanal) beyond the limits of the area of direct influence. How does the Project Owner plan to remedy the deficiencies in the definition of the area of influence?

According to the latest reports on production activity, the Maipo River Basin has an annual renewal capacity of approximately 4 million cubic meters of aggregates, which are extracted from the stretch passing through the districts of an José de Maipo, Pirque, Puente Alto, San Bernardo, Buin, and Isla de Maipo. How does

the Project Owner plan to remedy potential reductions in this resource? Other Remarks:

- * The information provided contains discrepancies (example: flow rate information).
- * Information on the hydrological analysis commissioned by the Project Owner is missing.
- * Information permitting the suitable analysis of impacts of activities and construction conducted between the mouth of the Colorado River and the water discharge point at Las Lajas, and their dependence on hydraulic conditions in the river.
- * Impact through the changes that will be caused in the sedimentation dynamics of the river system is neither provided nor evaluated.

In light of the Project's predicted effects modifying flow patterns, the following effects are expected to arise in the sedimentation equilibrium of the watercourses subject to intervention (Yeso, Colorado, and Maipo Rivers):

- * Reduction in flow rate in the Volcán, Yeso, and Colorado rivers downstream of the intakes of the Alfalfal II hydroelectric plant will result in a decline in sediment transport capacity. This means that there will be a reduction in the average predicted contribution of sediments flowing from the aforementioned watercourses into the Maipo River, which, particularly downstream of the Colorado River, equates to 15% of predicted transport in the Las Vertientes area, and 25% of potential transport in the San Bernardo area (as the study indicates)
- * A sharp rise in transport capacity in the Maipo River at the point of discharge of the hydroelectric plant (confluence of the Maipo River with the El Manzano Stream), resulting from the discharge of clean water from the power plants.
- * The analysis presented does not consider the creation of local imbalances in the tributaries of the Maipo River.

This will lead to the degradation of the riverbed of the Maipo River. None of these potential effects are addressed in the sedimentation study, and in the transport capacity through the incorporation of clean water. Similarly, the effects of imbalances introduced in the input of aggregates or the extent of the watercourse affected, are also not addressed.

Finally, regarding solid transport dynamics, influencing the erosion – sedimentation equilibrium and transport in downstream stretches, the Project Owner is requested to define the area of direct and indirect influence for this component, including the activities of settling areas, artisanal and mechanical aggregate material extraction, and other uses of the watercourse.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the

watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.06 Sediment**

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum.**

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study** presented in **Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfal Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential expected solid streambed wear/entrainment (transport capacity) in the rivers, calculated based on the theoretical modeling of their hydraulic characteristics

and theoretical numerical relationships.

2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (AGU.06.01), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted.

It can be concluded that the Maipo River system can be managed such that, With the Project operational, present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

AGU.06.04 Discharge effects

Water capture in advance of in-situ gravel removal leads first to a reduction in sediment load in water carried through the headworks to the turbine rooms, while the solid materials that is retained is returned to the river. At the point where water is discharged from the plants (Las Lajas area), water that has passed through the turbines - which contains a certain quantity of sediment - once again mixes with the water in the rivers, returning to its original conditions in terms of average sediment load (**Addendum, Section I, Question 28**).

At the point where water is returned to the Maipo River, in the Las Lajas area, there will be no degradation of the riverbed as it is composed entirely of rocks. It should be mentioned that the flow rate discharged from the PHAM at this point is always lower than the flow rate in the Maipo River just upstream.

During the operations phase of the Project, planned maintenance activities do not include any cleaning of tunnels and culverts. Inside the tunnels, the cross sectional area for water flow is small enough to prevent sedimentation. This is shown through the operation of the Alfalfa Plant for 20 years without any cleaning of the tunnels being included among maintenance activities.

The only operations that lead to the discharge of sediment are the discharge of gravel traps at the inlets, and the flushing of the sand traps, returning sediment to the river once a certain volume has built up within them. These operations are conducted intermittently and for short time periods (1 minute for sand traps, 10 minutes for gravel traps), at variable frequency depending on the season. For more information see the **Addendum, Section IV, Question 3**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water

abstracted from the
upper reaches of the La Engorda, Colina, Las Placas, and El Morado
Streams and the El Yeso River downstream of the El Yeso Reservoir, as well
as water from the

upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfafal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfafal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfafal I and Alfafal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

Remark N° 43

1. Tourism

- * The EIS underestimates not only the present importance of tourism in the district, but also its potential, associated with a lack of infrastructure; similarly, it fails to mention that the district's main attraction consists of its natural scenic beauty.
 - * The Project Owner must indicate current and potential tourism demand in the region, in both qualitative and quantitative terms.
 - * Determine tourism service availability in the context of demand.
- * Describe and classify the tourism companies with special interests considered in the district, and the promotion of tourism service provision in the area.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent

decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism**

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 44

2. Environmental Damage and Impact on Tourism

- * The death of rivers, intervention in the El Morado Natural Monument, the heaping up of 2,700,000 million m³ of muck, etc., are not cosmetic effects. Under Law 19,300, Art. 2, Part c, it is stated that "Environmental damage [means] any significant loss, decline, detriment, or harm caused to the environment, or to one or more of its components"
- * The Project Owner must define and distinguish between cosmetic effects and environmental damage.
- * Environmental damage will lead to a negative effect on tourism through the loss of landscape value and the absence of the area's typical ecosystems.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to

support outreach and awareness building of the District of San José de Maipo as a national tourism resource. Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents. F&F Biodiversity Impact**

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3, and Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neopteris curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Liolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopus cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

F&F.02.02 Form of mitigation

Aquatic flora and fauna

The Project calls for a suite of multi-purpose environmental management measures that aim to minimize its effects on living organisms, including: minimization of watercourse areas to be subject to intervention by prioritizing such works for late summer and early fall seasons (period of lowest flow rates), the adoption of special precautions to prevent accidental spillages into watercourses (prohibition of the storage of lubricant drums in or near watercourses, etc), and permanent maintenance of ecological flow rates.

For more detailed information, including technical documentation that complements the information described above, see Annex 17 of the Addendum.

Terrestrial Flora and Vegetation

In order to prevent and/or minimize the Project's effects on plant life, it plans to adopt a number of integrative measures: micro-routing in advance of starting work on-site, in order to identify specimens of plants listed in any conservation category and subject to impact; compensation with the planting of 10 specimens for every one destroyed, in the case of non-woodland species listed for conservation; implementation of a woodland management plan applicable to woodland areas, which describes its measures in accordance with Article 5 of the Woodland Law; implementation of vegetation restoration plans at muck disposal sites, encampments, artificial slopes, and tunnel access terraces (EIS, Annexes 7 and 29). More in-depth information on complementary measures is provided in Annex 6 of Addendum 1.

Terrestrial fauna

Specific wildlife environmental management measures have been proposed for each particular species, taking into account prior experience in the success of these measures in similar projects. These measures will be implemented in continual coordination with the Servicio Agrícola y Ganadero. Principal measures include: capture of individuals belonging to species of conservation interest for rescue and relocation; controlled perturbation actions; and habitat replacement. Other measures are based on the use of signage, training for Contractors, and contractual requirements for on-site supervision (see details in Section 6.4.1.6 of the EIS). See Annex 4 of the Addendum for the native wildlife rescue and relocation plan.

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.01 River sports

During the operations phase, the activities of the PHAM shall not directly or indirectly interfere with tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. Furthermore, the PHAM shall have no significant effect on boating activities on the Maipo River as a result of reductions in river flow rate; an analysis is presented in Annex 17 of the Addendum modeling a number of hydrological scenarios (1), concluding that the PHAM shall not affect the current situation in rafting and kayaking activities conducted in the area between San Gabriel and San José de Maipo.

In order to establish an analysis comparing the current Maipo River boating situation with predictions for the situation with the Project operational, the variables of flow rate, river width, and water depth were modeled, as valid indices to establish conditions for boating activities on the Maipo River.

This analysis showed that the Project shall not interfere with tourism activities conducted on the Maipo River, in view of estimates that in a dry year, the magnitude of variations in flow rate and water depth will not cause interference with boating activities.

For more information, see **Annex 17 of Addendum 1**.

- (1) The hydrological analysis used to evaluate reductions in flow rate is based on a statistical record going back 50 years, thus ensuring that seasonal and annual variations are incorporated into the analyses conducted.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training,

advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the

possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

TUR.03 Visual impact

The Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and continue throughout the working life of the Project. A qualitative methodology is used to study these effects, whereby the first phase consists of identifying sources of visual impact, and the second phase relates to identifying and classifying environmental impacts.

As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention.

As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access roads.

For further information on the methodology used for landscape impact assessment, see **Chapter 6, Section 6.1.4.10 of the EIS, and Annex 17 of**

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS**.

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfal, Aucayes, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions.

The Project's has been designed and engineered to include a suite of measures for the optimization of the construction of new roads; for further information on these measures, see **Chapter 2, point 2.3.2.5 of the EIS**.

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in these areas, demonstrating that no interference will arise, due mainly to the following considerations:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

Remark N° 45

3. Watercourses Subject to Intervention

- * Given that, in view of its characteristics and natural monuments, the Cajón del Maipo valley has been declared a ZOIT Zone of National Interest, the Project Owner is requested to analyze and evaluate to what extent the impacts to be generated by the PHAM in the area subject to intervention are compatible with the district's role as a tourism destination.
- * The AES Gener Colorado River installations abstract 100% of water from the Maitenes, and the company agrees to maintain an ecological flow rate of 0.7 m³/second, allowing the river to dry out almost completely. This situation is not, as AES Gener would have it, "a merely cosmetic effect visible from certain points", but rather leads to serious consequences affecting the area's tourism and economy. The entire south-east riverbank is an area with many scenic areas, and its natural beauty brings in a large influx of persons throughout the year. The Colorado Valley does not, as Gener states, require tourism infrastructure in order to be visited; Chilean and foreign tourists come to the Cajón del Maipo in search of our natural world. A trail winds along the length of the river, where hikers can find crofters' cottages selling goat cheese, viewpoints looking out over the river, places where condors can be sighted, horse riding routes, native woodland, sites where UFOs are said to be seen, and endemic flora and wildlife, all in a harmonious riverside ecosystem that is now going to disappear.
- * The same situation occurs once again in the El Morado Stream, which will be left with a flow rate of 0.24 m³/second, the La Engorda Stream with 0.2 m³/second, the Colina Stream with 0.3 m³/second, and the Las Placas Stream with 0.14 m³/second. If these ecological flow rates are permitted, these watercourses will dry out. This will lead to the disappearance of their ecosystems as well as their landscape and recreational value.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal.

Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual

Remark N° 66 Units of Measurement

The Environmental Impact Study should present all relevant figures on flow rates in a single unit of measurement, permitting clear comparison between the flow rates that the project plans to abstract as against the flow rates that exist in each river in each area of each valley that will be affected, from the Valle de las Arenas through to El Manzano.

It shows a lack of rigor to present some figures in liters per second (l/s) and others in cubic meters per second (m³/s).

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components

(stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a

conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **F&F Biodiversity Impact**

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3**, and **Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes

the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neoporteria curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo Spinolosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Liolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

SUE.02 Soils, meadows, and wetlands

The Project Owner has conducted a number of studies with the aim of characterizing the vegetation of summer grazing areas (La Engorda) (see details in Addendum 1, Annex 6, and in Chapter 5 of the EIS), as well as flora and vegetation studies in the Project's area of influence (EIS, Chapter 5).

These studies contain information compiled in fieldwork campaigns conducted in Fall 2005, Spring 2006, November 2007, March 15 and 16, 2008, and September 2008, which add to the body of knowledge available regarding vegetation in these areas.

The Lo Encañado area shall be assigned a status of controlled access area for works contractors at all times: it shall not be subject to any intervention whatsoever. For more information on vegetation areas that could be affected by the construction works, and to learn about mitigation measures proposed by the Project Owner, you are advised to review Annex 42 of the EIS and Annex 6 of the Addendum.

With regard to environmental regulations that apply specifically to vegetation and plant life, the Project Owner shall be subject to: **Supreme Decree 366** (Exploitation of Tamarugo, Carob, Chañar, Guayacán, Aextoxicon, Charcoal, Acacia, Boldo, Maiten, Litre, Bollen, and Quillay). This legal instrument governs the felling of trees and bushes.

Supreme Decree 4363 and D.L 701 (Approving the Definitive Text of the Law on Woodland and Regulations on Forest Promotion).

Article 2 of the Woodland Law establishes an obligation that land classified as for preferential woodland land use, as well as natural and artificial woodlands, are subject to woodland management plans approved by the National Forestry Commission (CONAF). Furthermore, Article 21 of Decree Law 701 establishes that any felling or usage of native woodland shall be subject to the CONAF's prior approval of the corresponding management plan.

Decree 82 (Prohibiting the Felling of Trees and Bushes in Indicated Andean High Mountain and Foothill Areas)

Article 102 Sector Environmental Permit (Permit for the felling or exploitation of native woodland, in any type of land, or plantations located in land with preferential characteristics for woodland use).

For further information and analysis on the aforementioned regulations and permits, as applicable to the Project, as well as in terms of general aspects, compliance, and regulatory bodies, please see Sections 3.2.6 and 3.3.7 in Chapter 3 of the EIS.

TUR Tourism

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district;

that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of

natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán. For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.01 River sports

During the operations phase, the activities of the PHAM shall not directly or indirectly interfere with tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. Furthermore, the PHAM shall have no significant effect on boating activities on the Maipo River as a result of reductions in river flow rate; an analysis is presented in Annex 17 of the Addendum modeling a number of hydrological scenarios (1), concluding that the PHAM shall not affect the current situation in rafting and kayaking activities conducted in the area between San Gabriel and San José de Maipo.

In order to establish an analysis comparing the current Maipo River boating situation with predictions for the situation with the Project operational, the variables of flow rate, river width, and water depth were modeled, as valid indices to establish conditions for boating activities on the Maipo River.

This analysis showed that the Project shall not interfere with tourism activities conducted on the Maipo River, in view of estimates that in a dry year, the magnitude of variations in flow rate and water depth will not cause interference with boating activities.

For more information, see **Annex 17 of Addendum 1**.

- (1) The hydrological analysis used to evaluate reductions in flow rate is based on a statistical record going back 50 years, thus ensuring that seasonal and annual variations are incorporated into the analyses conducted.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

TUR.03 Visual impact

The Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and continue throughout the working life of the Project. A qualitative methodology is used to study these effects, whereby the first phase consists of identifying sources of visual impact, and the second phase relates to identifying and classifying environmental impacts.

As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention.

As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access roads.

For further information on the methodology used for landscape impact assessment, see **Chapter 6, Section**

6.1.4.10 of the EIS, and Annex 17 of Addendum 1.

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS**.

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfal, Aucayes, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions.

The Project's has been designed and engineered to include a suite of measures for the optimization of the construction of new roads; for further information on these measures, see **Chapter 2, point 2.3.2.5 of the EIS**.

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in these areas, demonstrating that no interference will arise, due mainly to the following considerations:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

Remark N° 46

4. Impact on the El Manzano Area

- * The El Manzano Channel intake is linked to the Colorado River's hydrological system, providing irrigation water to the 292 hectare area that makes up the El Manzano area.
- * Due to the decline in flow rate in the river, works must be constructed in order to permit the abstraction of water over which rights are held, yet the company AES Gener refuses to enter into any kind of economic agreement relating to the maintenance of these installations, leaving the community economically and technically responsible for maintaining its irrigation system. If this problem is not solved, El Manzano will become a desert, rather than the green pasture that it is today. This will certainly affect all trade and the area's tourism companies, as they are absolutely dependent on keeping their surroundings green.
- * The Project Owner is requested to attach a layout map of the companies present in this area, fruit orchards, plant nurseries, camp sites, picnic areas, restaurants, bee keepers, producers of jams/jellies and nuts and nuts or dried fruits, animal feed plants, etc, which directly or indirectly depend on irrigation water for their production processes or additional value added.
- * Attach a layout map of properties that depend on irrigation water to maintain their scenic value.
- * Establish a system of compensation to mitigate the impact leading to declines in property values and in quality of life.

Thematic responses

Specific response

In conformity with commitments made in meetings held with the management of the El Manzano Channel at the offices of Gener between January and October 2008, Gener has agreed to underwrite the construction of new infrastructure necessary in order to ensure water capture from the Colorado River to which that community possesses legally granted rights, as well as to pay all additional maintenance costs that the community may incur as a consequence of the operation of the PHAM. Furthermore, Gener will pay all additional costs payable by the community to the DGA for corresponding permit applications.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4 in Chapter 2 of the EIS**.

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that is, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**).

AGU.02.02 “Hanging” channels

Gener has repeatedly issued declarations that it is aware that not only the works that it

shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by

community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.03 Decline in land value

Road conservation activities planned shall not involve urban areas. Road conservation activities shall be implemented mainly along mountain roads, particularly on the Alto Volcán area and El Yeso Reservoir access routes (Route G-25 and Route G-455, respectively).

Road widening actions are not planned, given that, according to the Project's Basic Engineering Studies, the roads subject to conservation works have a wide enough roadway for the passage of trucks, as defined by the Highways Department; therefore, no expropriation of land will take place.

With regard to land values, it can be stated that lots located alongside Route G-345 have increased in value significantly with the development of the access route to Maitenes and Alfalfal.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. In parallel, the study investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

Remark N° 47

5. Labor Hiring

The Project Owner overestimates job creation, whereas the contractor and not the company itself shall be in charge of hiring. Gener must:

- * Quantify the amount of labor that it shall hire in the district.
- * Describe the positions to be filled.

* Establish a binding agreement between the Project Owner and the Municipal Government whereby Gener agrees to source 100% of the persons who have registered at the labor brokerage office.

Thematic responses

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

SOC.01.01 Requirements

In view of the characteristics and scale of the Project, personnel with specific qualifications will be required for the operation and maintenance of plant machinery and equipment, during the operations phase. Conversely, during the Project Construction Phase, it is projected that labor requirements will create jobs not only for mining workers, but also for machinery operators, drivers, and both skilled and unskilled construction personnel, the latter working mainly as day laborers and assistants.

The population of the Project's area of direct influence has been found to possess levels of training and specialization (occupation as defined under the CIIU code) that shall permit them to access both skilled and unskilled work positions created by the Project.

SOC.01.02 Working conditions

To date no schedule exists specifying labor requirements for the full duration of the construction phase. Detailed information specifying jobs created under average and peak labor requirements, broken down by labor requirement dynamics for each encampment, will only be available once the Project Owner has tendered the works contracts.

During the operations phase, it is expected that personnel requirements will amount to approximately 80 positions available, required for power plant operations and maintenance activities. Unlike work positions created during the construction phase, the jobs created in the operations phase will be permanent (EIS, Chapter 6, Section 6.4.2.4).

The Project Owner will provide for coordination between the construction works contractors, the Labor Brokerage Office, and the Municipality of San José de Maipo, regarding local labor required and jobs sought. The PHAM has accepted a commitment to incentivize works contractors to prioritize local contracting of labor required.

No prior training is planned in advance of the Construction Phase. However, such training will form part of the programs implemented in the more advanced phases of the project.

Remark N° 48

6. Maitenes Foundation

The funds that Gener is offering to finance education and tourism projects should not be handled by its Maitenes Foundation. A foundation should be formed that is external to the company, representing not only Gener but also the principal community organization in the district, and the Municipal Government.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

CAL.02 Education

A goal of the Maitenes Foundation relates to education for children and young people against the backdrop of the natural environment (for more information on the goals and achievements of the Foundation, see Annex 26 of the EIS).

Gener firmly believes that contributions to the technical and vocational education and training of young people must keep sight of real employment possibilities. Therefore, as a first initiative it has earmarked resources for an education improvement project in the district, which will contribute to establishing education management for the restructuring of the school curriculum and professional technical capacity building, taking into account the features needed to boost local employability. Based on information and recommendations from this study, Gener, acting through the Maitenes Foundation, will undertake a Capacity Building for Employability Program fundamentally oriented towards those whose family, social, or economic situation has barred them from completing their education and training, or acquiring the skills needed in order to find work.

Remark N° 49

7. Supply Purchase Agreements

The Project Owner overestimates the benefit that will be generated for the community through the purchase of supplies and the presence of 20 encampments.

The Project Owner should enter into a binding agreement with the SJM Chamber of Commerce and Tourism, agreeing that all supplies required in the functioning of the encampments shall be acquired in the district.

Thematic responses

Specific response

The Project owner is not able to agree to this request because it goes against the concepts of free competition, and it is also unable to oblige contractors to purchase their supplies in the district.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent

decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.05 Promoting entrepreneurship

The company has agreed to use its **Fundación Maitenes** foundation to set aside an **annual fund over a 10 year period starting in 2010**, to support local residents who formulate tourism development business plans for implementation in the area. These projects will be financed through funds open for competitive tenders; submissions will be evaluated on their own merit by a council of community representatives, which will select which projects will be funded.

The initiative to be implemented by the Fundación Maitenes may be linked to projects in progress run by public institutions and services in the district, related to the two lines of action that the foundation has agreed to support. This linkage may help to strengthen state-run initiatives and foster sustainability over the course of time for the actions supported by the foundation, during the period in which the program is active.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. In parallel, the study investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 50

8. El Morado Natural Monument

- * The construction and operation of the El Volcán Tunnel underneath the El Morado Natural Monument (a SNASPE site) is not compatible with the environmental conservation objectives defined in legal instruments in force in the country.
- * This should not be evaluated as an environmental impact, but rather in terms of requirements stipulated in conservation legislation.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

PRO.01 Regulations

A plan has been prepared addressing compliance with environmental regulation legislation applicable to the Project, as stipulated and specified in Article 12 part g) of Law 19,300, and Article 12 part d) of Ministry of the General Secretariat of the Presidency of the Republic Supreme Decree 95.01, which sets the recast text of the Regulations on the Environmental Impact Evaluation System (RSEIA), indicating the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and the sector environmental permits that the Project will require for its execution (EIS, Chapter 3, Section 3.1)

Chapter 3 of the EIS provides detailed information on:

- The legal framework within which the Project was designed;
- The oversight bodies tasked with enforcing compliance in matters subject to regulation;
- The ways in which the Project will ensure compliance with these regulations.

The Project Owner is obligated to comply strictly with legislation in force, and the bodies tasked with enforcing this compliance are the governmental and state bodies specified in the same legislation.

Remark N° 51

9. Characterization of Impact on the El Morado Natural Monument

Environmental impact should be characterized with regard to:

- * The rate at which damage occurs, with the aim of modeling regeneration capacity.
- * The extent to which the impact is irreversible, and the damage universal. This impact affects not only a specific location, but also the nation's heritage.

Thematic responses

Specific response

The PHAM shall have no effect on the El Morado Natural Monument as its presence in this area will be limited to a tunnel passing under the area at a great depth.

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas,

Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.02 Tunnels

The majority of the Project is planned for installation underground. The general characteristics of the tunnels are described in Chapter 2 of the EIS, Table 2.2.5 (for detailed geological information on the path taken by the tunnels, see Annex 46 of the EIS).

For an evaluation of the impact and environmental management measures associated with underground installations, see Chapter 6 of the EIS.

Annex 45 of the EIS, Hydro-Geology of Underground Works, presents a general description of the geological conditions that are expected to be found along the lengths of the tunnels; expected permeability based on geological knowledge and hydro-geological conditions in the area, incorporating experience gained during the construction of tunnels for the Alfalfal Plant, which has been operative for more than 17 years; as well as a description that includes the design of the tunnels, providing a brief explanation of the methods to be used to reduce and control water seepage.

With regard to the impact of the path taken by the tunnel passing underneath the El Morado Natural Monument, and measures to be taken to respect the area, see Section I, Responses 4, 5, and 6, in the Addendum.

Remark N° 52

Labor Hiring

The contractor and not the company itself shall be in charge of hiring. Gener

- must: a) Quantify the amount of labor that it shall hire in the district.
b) Describe the positions to be filled.

c) Establish a binding agreement between the Project Owner and the Municipal Government whereby Gener agrees to source 100% of the persons who have registered at the labor brokerage office.

Thematic responses

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

SOC.01.01 Requirements

In view of the characteristics and scale of the Project, personnel with specific qualifications will be required for the operation and maintenance of plant machinery and equipment, during the operations phase. Conversely, during the Project Construction Phase, it is projected that labor requirements will create jobs not only for mining workers, but also for machinery operators, drivers, and both skilled and unskilled construction personnel, the latter working mainly as day laborers and assistants.

The population of the Project's area of direct influence has been found to possess levels of training and specialization (occupation as defined under the CIIU code) that shall permit them to access both skilled and unskilled work positions created by the Project.

SOC.01.02 Working conditions

To date no schedule exists specifying labor requirements for the full duration of the construction phase. Detailed information specifying jobs created under average and peak labor requirements, broken down by labor requirement dynamics for each encampment, will only be available once the Project Owner has tendered the works contracts.

During the operations phase, it is expected that personnel requirements will amount to approximately 80 positions available, required for power plant operations and maintenance activities. Unlike work positions created during the construction phase, the jobs created in the operations phase will be permanent (EIS, Chapter 6, Section 6.4.2.4).

The Project Owner will provide for coordination between the construction works contractors, the Labor Brokerage Office, and the Municipality of San José de Maipo, regarding local labor required and jobs sought. The PHAM has accepted a commitment to incentivize works contractors to prioritize local contracting of labor required.

No prior training is planned in advance of the Construction Phase. However, such training will form part of the programs implemented in the more advanced phases of the project.

Remark N° 53 Maitenes Foundation

The funds that Gener is offering to finance education and tourism projects should not be handled by its Maitenes Foundation. A foundation should be formed that is external to the company, representing not only Gener but also the principal community organization in the district, and the Municipal Government.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

CAL.02 Education

A goal of the Maitenes Foundation relates to education for children and young people against the backdrop of the natural environment (for more information on the goals and achievements of the Foundation, see Annex 26 of the EIS).

Gener firmly believes that contributions to the technical and vocational education and training of young people must keep sight of real employment possibilities. Therefore, as a first initiative it has earmarked resources for an education improvement project in the district, which will contribute to establishing education management for the restructuring of the school curriculum and professional technical capacity building, taking into account the features needed to boost local employability. Based on information and recommendations from this study, Gener, acting through the Maitenes Foundation, will undertake a Capacity Building for Employability Program fundamentally oriented towards those whose family, social, or economic situation has barred them from completing their education and training, or acquiring the skills needed in order to find work.

Remark N° 54

El Manzano Environmental Impact Study

The EIS presented by Gener does not include impact that will be generated by the PHAM at El Manzano. The

EIS should include:

1. Identification, prediction, interpretation, mitigation plan, and evaluation of the impact that will be caused, particularly with regard to irrigation systems.
2. Actions that shall be taken to mitigate the significant negative impacts that will be generated by the PHAM.

Thematic responses

Specific response

In conformity with commitments made in meetings held with the management of the El Manzano Channel at the offices of Gener between January and October 2008, Gener has agreed to underwrite the construction of new infrastructure necessary in order to ensure water capture from the Colorado River to which that community possesses legally granted rights, as well as to pay all additional maintenance costs that the community may incur as a consequence of the operation of the PHAM. Furthermore, Gener will pay all additional costs payable by the community to the DGA for corresponding permit applications.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in **Chapter 2 of the EIS**.

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that it, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02 channels

"Hanging"

Gener has repeatedly issued declarations that it is aware that not only the works that it

shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

PRO.02 EIS Additional and Complementary Information

In accordance with consultation procedures conducted by oversight services, further studies and information have been incorporated into Addendum 1, which complements existing information provided in the EIS. Regarding ecological flow rates (**Annex 17**), cultural heritage (**Annex 14**) and the management of summer grazing areas (**Annex 6**).

Remark N° 55 Irrigation User Organizations: El Manzano Channel and Maurino Channel

In view of the drop in water flow in the Colorado River, irrigation user organizations will find it impossible to abstract the quantities of water to which they have rights.

1. The Project Owner should include the construction of such installations as shall be necessary to avoid this impact, and the commitment that has been expressed to defray all costs arising through the construction and maintenance of these installations.
2. The Project should include guarantees and compensation payable in the event that these organizations are rendered unable to abstract the water to which they hold rights.
3. The Project Owner should attach written consent by the "El Manzano Channel" and "Maurino Channel"

Thematic responses

Specific response

In conformity with commitments made in meetings held with the management of the El Manzano Channel at the offices of Gener between January and October 2008, Gener has agreed to underwrite the construction of new infrastructure necessary in order to ensure water capture from the Colorado River to which that community possesses legally granted rights, as well as to pay all additional maintenance costs that the community may incur as a consequence of the operation of the PHAM. Furthermore, Gener will pay all additional costs payable by the community to the DGA for corresponding permit applications.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02 "Hanging" channels

Gener has repeatedly issued declarations that it is aware that not only the works that it shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

PRO.01.01 Compensation

The concept of compensation refers to the act of indemnifying damages or harm caused. Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS).

In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

Remark N° 56 Colorado River EIS

- * The impact to arise as a result of the decline in flow rates in the Colorado River is not a cosmetic effect that is justified through the absence of tourism-related infrastructure.
- * The Project Owner must provide documented background information forming the grounds for the prediction, identification, and interpretation of the impact that these actions shall cause.
- * It should also describe the actions that it shall take in order to prevent or minimize all significantly negative effects.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services. For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of**

flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention

under the PHAM consists of maintaining an ecological flow rate (Q_e) approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility
(Addendum, Section 5,

Question 2).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
	Alto Volcán		
	Stream gauge station		
	406,157	6,259,100	
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum.CAL Impact on Quality of Life**

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plant (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as

they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be

increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **PRO.01.01 Compensation**

The concept of compensation refers to the act of indemnifying damages or harm caused. Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS).

In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.01 River sports

During the operations phase, the activities of the PHAM shall not directly or indirectly interfere with tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. Furthermore, the PHAM shall have no significant effect on boating activities on the Maipo River as a result of reductions in river flow rate; an analysis is presented in Annex 17 of the Addendum modeling a number of hydrological scenarios (1), concluding that the PHAM shall not affect the current situation in rafting and kayaking activities conducted in the area between San Gabriel and San

José de Maipo.

In order to establish an analysis comparing the current Maipo River boating situation with predictions for the situation with the Project operational, the variables of flow rate, river width, and water depth were modeled, as valid indices to establish conditions for

boating activities on the Maipo River.

This analysis showed that the Project shall not interfere with tourism activities conducted on the Maipo River, in view of estimates that in a dry year, the magnitude of variations in flow rate and water depth will not cause interference with boating activities.

For more information, see **Annex 17 of Addendum 1**.

- (1) The hydrological analysis used to evaluate reductions in flow rate is based on a statistical record going back 50 years, thus ensuring that seasonal and annual variations are incorporated into the analyses conducted.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 57

Ecological flow rate: Colorado River

- * The ecological flow rate should be defined by the DGA, not by the Project Owner
- * The point where this flow rate is to be measured and monitored should be sited at the mouth of the Colorado River.
- * Flow rate monitoring should include the participation of outside agencies, that are not hired by the company.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate time series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of**

flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Q_e) approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Northing	Easting
	Alto Volcán	406,157	6,259,100
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 58 Yeso River EIS

- * Gener holds rights over water in the Yeso River amounting to 15 m³/sec. These rights were granted without ecological flow rate requirements. The Project plans to abstract 15 m³/sec of water 700 m downstream of the reservoir. An impact that leads to the death of a river is not a cosmetic effect, as the Project Owner would have it:
- * The Project Owner must provide documented background information forming the grounds for the prediction, identification, and interpretation of the impact that implies the death of the Yeso River.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4 in Chapter 2 of the EIS.**

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been

conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs,

zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of flow rates and water levels**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For more information, see **Annex 17 of the Addendum**.

Remark N° 59

Ecological flow rates: Colina, Engorda, Las Placas, and El Morado Streams

* The flow rates proposed by the Project Owner would alter conditions in the watercourse, impede the development of living components of the ecosystem (plants and animals), and would affect the dynamics and functioning of the ecosystem.

* The Project Owner should describe the actions that it shall take in order to mitigate all significantly negative effect resulting from declines in flow rate.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of

the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

AGU.04.04 Monitoring and control of flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Q_e) approved by the DGA. In the case of the PHAM,

the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses. Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Eastings	Northing
	Alto Volcán	Stream gauge station	6,259,100
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

F&F Biodiversity Impact Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02.01 Impact Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to

intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly

reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

Remark N° 60

Effects on the Quality of Life in the Baños Morales Community

It is stipulated in Law 19,300, Article 11, parts d and e:

Projects or activities shall require the preparation of an Environmental Impact Study if they generate or lead to at least one of the following effects, characteristics, and circumstances:

- a) Localization close to a settlement or protected natural resources subject to impact, as well as the environmental value of the area in which they are planned to be implemented;
- b) Alteration of the area's landscape or tourism value, of significant magnitude or duration.

No part of the EIS prepared by AES Gener makes reference to the human impact that this project shall cause affecting the quality of life in the settlement of Baños Morales, with the installation of an encampment housing 500 persons close to the community, under circumstances that by law require the preparation of an Environmental Impact Study.

It is therefore requested that the corresponding study be conducted, in order to determine the concrete way in which we as a community shall be affected.

Thematic responses

Specific response

There shall be no direct impact in the settlement of Baños Morales as there shall be no encampments or traffic flow close to the area.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the

dynamism of all activities in the District of San José de Maipo; iii)
Improvement in quality of life for many families, as family members
return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.02 Human contingent presence

The presence of Project employees will be temporary (limited both to the years of the construction phase, and to the working day organized into shifts), thus disincentivizing them and their families from moving to the area on a permanent basis. During the Project's construction phase, its employees shall sleep in the encampments described in the documentation, not making use of existing hotels and hostels located in and near the area's settlements.

Once the construction phase has been completed, the Project's installations and encampments shall be removed; they shall therefore not become part of existing settlements, or form new centers for the formation of settlements.

The PHAM plans call for the creation of 5 encampments, located away from settlements. These encampments will be operated as described in Annex 33, and each will house a permanent contingent of 200-400 employees, under the standard working regime adopted by mining installations. The transport of employees from the encampments to their places of residence shall have a frequency determined in accordance with the working shifts. Therefore, it is important to understand that under no circumstances shall the presence of Project employees in the area lead to the type of interaction with

the resident community and demand for local services that currently occurs as a result of the flow of tourists and visitors, mainly during weekends, holidays, and the summer season.

In view of the above, the Project shall not lead to the following potential impacts: overpopulation at a local or district level (in existing settlements); or effects modifying local customs, economic service provision activities, connectivity, and local load capacity (understood to refer to the load placed on infrastructure and equipment).

As indicated in Annex 39 of the EIS, documentation supporting the analysis described above shall form part of activities under the Social Indicator Monitoring (SIM) program. This monitoring program is based on compiling information using qualitative and quantitative techniques developed in the field of Social Sciences, oriented towards investigating a suite of indices that pay due heed to trends in relevant variables for monitoring, selected in accordance with the characteristics of the Project and of the communities in the area where it is to be implemented. Reports will be issued twice per year containing the results obtained, including the use of graphical aids to show comparative changes in parameters from one study campaign to the next. This document will be delivered to CONAMA.

In general, by gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project may cause in its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities.

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.03 Visual impact

The Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and

continue throughout the working life of the Project. A qualitative methodology is used to study these effects, whereby the first phase consists of identifying sources of visual

impact, and the second phase relates to identifying and classifying environmental impacts. As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention.

As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access roads. For further information on the methodology used for landscape impact assessment, see **Chapter 6, Section 6.1.4.10 of the EIS, and Annex 17 of Addendum 1.**

Remark N° 61

Transmission lines

Under Article 10 of Law 19,300: Projects or activities that may cause an environmental impact, during any of their phases, and which are subject to the environmental impact evaluation system, are as follows:

- a) High voltage electricity transmission lines and associated substations.
- b) The EIS prepared by Gener makes no mention whatsoever of the impact to be caused by the temporary high voltage electricity lines that will run from Route G-25 to the encampment located in the La Engorda Valley, or the permanent lines that will run from Route G-25 to each of the intakes located in that Valley.

The study is not complete.

Thematic responses

ELE Electrical Installations

The electrical installations presented in the EIS comprise the substation, to be located in the El Sauce area, the characteristics of which are to be found in **Annex 27 of the EIS**; given that the electricity transport layout (cabling and towers) is to be presented to the Environmental Impact Assessment System once all background information is available.

ELE.03 Transmission lines

In view of the project's location, close to Santiago, it is expected that the distance covered by the definitive cabling layout will be short, involving a minimum of sectors not subject to prior intervention. With regard to the specific location of the cabling layout, plans call for the use of the existing high tension power line used by the Queltehues, Volcán, and Maitenes Plants.

Once the layout of the high tension power line has been defined, the Project Owner will submit this plan to the Environmental Impact Assessment System, in accordance with legislation in force. In line with the development of the Compliance Plan for environmental legislation applicable to the Project, the General Regulations applicable in this instance are indicated below:

Decree with Force of Law N°4, dated 05 February, 2007, setting forth the Recast, Coordinated, and Systematized Text of the General Law on Electrical Services.

The General Law on Electrical Services governs the generation, transmission, distribution, and regimen of concessions and tariffs applicable to electrical energy, and the functions of the State with regard to these areas.

Supreme Decree N° 327, Regulations Regarding the General Law on Electrical Services

The Regulations Regarding the General Law on Electrical Services establish, in their 8th Article, that hydroelectric power plants, electrical substations, and transmission lines may be installed without making a request for a concession, when the interested party wishes. These concessions may be provisional (in order to study projects) or definitive. A definitive concession is granted by a supreme decree issued by the Ministry of the Economy, by order of the President of the Republic. Permits relating to electrical installations that do not require concessions are granted by the corresponding Municipal Governments.

For further information and analysis on the aforementioned regulations, with regard to the Project, as well as in terms of general aspects, compliance, and regulatory bodies, please see **Sections 3.1.6 and 3.1.7 of Chapter 3 of the EIS**, where more detailed versions of this information can be found.

Remark N° 62 Legal Framework, Actions to be Taken to Comply with Regulations in Force

During the evaluation of the possible environmental impact that would arise through the implementation of the Project, it is necessary to bear in mind the legal framework in which it will exist, and which affects the area where construction is to take place. The relevant legislation is:

Ministry of Mining Supreme Decree 78, which declares the area of the Cajón del Maipo as an "area of scientific interest for mining purposes", including statements that:

"... The area is found to be a natural biodiversity reserve of international interest, and it provides significant ecosystem services to the Metropolitan Region, such as the storage and supply of fresh water for irrigation and human consumption. It also forms part of an area of interest for tourism and cultural interests, making possible environmental education and with scientific potential, as well as cultural and archeological riches. Thirdly, the real protection of this area will permit proof of compliance with Free Trade Agreements, and will constitute compliance with international cooperation requirements".

The area is also protected under the Andean Santiago Action Plan, which declares the Cajón del Maipo as a "priority site for biodiversity conservation". This resolution underpins COREMA's commitment to treating the Cajón del Maipo valley as a protection priority.

Considering that these two documents clearly espouse the State's commitment to the protection of this area, as its protection even permits accreditation and compliance with Free Trade Agreements, meaning that any disaster that might occur would affect not only the area itself but also would probably harm international relations, in terms of both trade and other areas.

Weighted consideration must therefore be given to the potential dangers that could affect the country through non-compliance with this commitment - dangers that could affect the economic, environmental, social, cultural, and political spheres. The Environmental Impact Study includes some of these aspects, but this point should be analyzed in greater depth, and evaluating all potential consequences.

Similarly, the actions that AES Gener plans to take in order to comply fully with the aforementioned legal requirements should be explained.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

AGU.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum**.

1.

**F&F Biodiversity Impact
Flora and Fauna**

The study conducted found evidence of the presence of 258 species of

plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.01 Regulations

The Project Owner shall comply with all legal environmental and sector-based regulations and requirements in force and applicable to the Project during the different phases of its development. The Project Owner has guaranteed compliance with the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and compliance with sector environmental permits.

Environmental regulations that apply to the Project have been identified based on its activities' potential environmental impacts affecting flora and fauna.

The full extent of these regulations is included in **Chapters 3 and 4 of the EIS, and in Section 2, Question 1 in Addendum 1.**

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.01 Regulations

A plan has been prepared addressing compliance with environmental regulation legislation applicable to the Project, as stipulated and specified in Article 12 part g) of Law 19,300, and Article 12 part d) of Ministry of the General Secretariat of the Presidency of the Republic Supreme Decree 95.01, which sets the recast text of the Regulations on the Environmental Impact Evaluation System (RSEIA), indicating the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and the sector environmental permits that the Project will require for its execution (EIS, Chapter 3, Section 3.1)

Chapter 3 of the EIS provides detailed information on:

- The legal framework within which the Project was designed;
- The oversight bodies tasked with enforcing compliance in matters subject to regulation;
- The ways in which the Project will ensure compliance with these regulations.

The Project Owner is obligated to comply strictly with legislation in force, and the bodies tasked with enforcing this compliance are the governmental and state bodies specified in the same legislation.

Remark N° 63 Social and Environmental Impact

Impacts associated with the abstraction of large quantities of water must be evaluated in environmental terms and in terms of biodiversity.

The Environmental Impact Study should be expanded to include consideration of the social and environmental effects currently clearly shown in the different areas of the Cajón del Maipo Valley, and the predicted situation with the Project in operation during different seasons of the year. It is not sufficient simply to show numbers; this material should include photographs that clearly show the predicted situation with and without the Project's effects on flow rates in, for example, the Volcán River, the Colorado River, and the Maipo River, in different parts of the valley.

One effect that may be of use as an example is that, considering the predicted summer flow levels, it will be possible for persons and animals to cross the rivers by wading. Certain areas bordering the rivers currently use them as natural boundaries. In order to mitigate this situation and prevent passage on foot, consideration should be given to installing fencing along the full extent of the riverbanks, which would have an enormous effect downstream of the Project, in almost all of the Cajón del Maipo Valley - let alone the costs that AES Gener would have to bear.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water

quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality).

Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of flow rates and water levels**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
	Alto Volcán		
	Stream gauge station		6,259,100
	406,157		
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

F&F Biodiversity Impact Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1**. The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the

work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS**.

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfa, Aucayes, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions.

The Project's has been designed and engineered to include a suite of measures for the optimization of the construction of new roads; for further information on these measures, see **Chapter 2, point 2.3.2.5 of the EIS**.

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in these areas, demonstrating that no interference will arise, due mainly to the following considerations:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

Remark N° 64

Siting, Tunnel Access, Encampments, Muck Disposal Heaps, and Intakes in the El Morado Area (Upper Volcán River)

Figure 2.2.1.2, from Chapter 2 of the EIS.

As shown in the figure, the location of the tunnel access, El Morado Stream Intake, Las Placas Stream Intake, Colina Stream Intake, La Engorda Stream Intake, and the site of Muck Disposal Heap 1, along with the corresponding encampment, together form an area of five (5) square kilometers where the construction activities and permanent operations of AES Gener will be located.

This area is crossed by a dirt road that has been in existence for years, and which is currently used by tourists traveling to the El Morado Glacier and El Morado Lake, a site of natural beauty and a tourist attracting that brings in many visitors, both Chilean and foreign.

This track is also used by mountain climbers, who engage in a variety of sports and training activities in the Mesoncito Valley and the Morado, Rubilla, Unión, Punta Italia, Punta Chile, Yamakawa, Mesón Alto, and Loma Larga mountains, as well as other nearby peaks.

AES Gener must clearly indicate the actions that it will take (if these installations are built) to allow these tourists to retain current conditions of free and zero-cost access - which is normally conducted on foot or on horseback, without requesting any permits of any kind from any institution or similar, without barriers or rangers requesting identification.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services

related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism**

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1**. The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS**.

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in

Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfal, Aucayes, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions. The Project's has been designed and engineered to include a suite of measures for the optimization of the construction of new roads; for further information on these measures, see **Chapter 2, point 2.3.2.5 of the EIS**.

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in these areas, demonstrating that no interference will arise, due mainly to the following considerations:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

VIA.04 Damage to roads and trails

The level of intervention to be generated by the Project was determined based on levels of saturation and deterioration of service levels, arising as a result of vehicle traffic caused by the Project - this Project highway impact analysis therefore did not take into account wear and tear on the road surface, as this parameter is not relevant when truck traffic complies with weight limits established by the Ministry of Public Works' Highways Department. In this regard, the Project Owner will permanently supervise weight control, in order to ensure compliance with the stipulations made in Ministry Public Works Supreme Decree 158/1980 which establishes gross weight limits for highways, as well as Decree 200, dated July 1993 and Decree 396, dated November 1993, establishing gross weight limits for urban streets. In both cases vehicle weight may not exceed 45 tons. For more information on measures planned by the Project Owner to ensure compliance with these regulations, see specific information in **Chapter 3 of the EIS**.

Furthermore, the Project Owner plans to undertake the conservation of Route G-25 (El Volcán area) and Route G-455 to the El Yeso Reservoir. Details of the current condition of each of these routes and planned road conservation measures, see the Road Improvement Program, in **Annex 19** of the EIS.

Finally, in advance of the start of road conservation activities, the corresponding Projects were approved by the Santiago Metropolitan Region Regional Highways Department. With regard to areas of interest for tourism, the conservation of part of the highway network and year-round maintenance of the more remote stretches of Route G-455 to El Yeso and Route G-25 from El Yeso Bridge to the El Volcán area will improve accessibility, favoring an increase in influx of visitors or the arrival of visitors over lengthier periods of the year, as these areas are largely inaccessible to tourists for a significant part of the winter season.

VIA.05 Free transit

The PHAM shall not interrupt access by mountain climbers, hikers, or permanent or sporadic visitors who enter the area for leisure, sports, cultural activities, etc. For safety reasons, the PHAM will restrict access only to its installations and work sites. Similarly, there will be no restrictions on access to properties owned by third parties and used for livestock grazing; in other words, usage conditions in summer and winter grazing areas have always been subject to agreements between livestock herders and landowners, and this situation will not be modified by the Project.

Remark N° 65 Water Rights

The EIS should contain information on rights to all water to be diverted; these rights should be duly registered in the name of AES Gener, or supplemented with title deeds and assignment documentation covering the quantity of water described in the EIS.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively.

Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 of the year 1990, with Registry Number 202 in the Public Registry of Water Usage Rights (available for examination in **Section V, Question 24, Section vi of the Addendum**).

Management Plan that contributes to the neutralization of certain existing environmental liabilities.

AGU.04.04 Monitoring and control of flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility

(Addendum, Section 5, Question 2).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility

(Addendum, Section 5, Question 2).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
	Alto Volcán		
	406,157		Stream gauge station
	La Engorda Stream Bridge		6,259,100
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 67 Determination of Ecological Flow Rates

Summer ecological flow rates (minimum annual flow rate) must be determined on a periodic basis by the Directorate General of Water (DGA), not by the Project Owner.

An ongoing study running over several years is necessary in order to determine ecological flow rates, taking into account variables such as rainfall patterns and seasonality of river flow; this study must be approved by the DGA.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs,

zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

Remark N° 68 Volcán River Water Abstraction

On page 3, paragraph 1 of the executive summary, it is stated that eleven (11) m³/s of water will be abstracted from the tributaries of the Volcán River (Engorda, Colina, Las Placas, and El Morado Streams); this could lead to enormous problems for the area, given that during at least eight (8) months of the year the average flow rate in the Volcán River, according to data obtained from the Directorate General of Water (DGA), is indicated to be close to ten (10) m³/s.

The EIS released by AES Gener ought to take into account the fact that this mountain river exhibits a variable flow regime, and the abstraction of a quantity greater than the quantity of water supplied by its tributaries from which it is captured would be completely unfeasible and dangerous, not only for the community and the environment but also for the Project itself.

This also indicates a lack of due attention to detail in the preparation of the EIS.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications

in the natural state of the hydrological system relate to the presence of the Alfafal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of

Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.02 EIS Additional and Complementary Information

In accordance with consultation procedures conducted by oversight services, further studies and information have been incorporated into Addendum 1, which complements existing information provided in the EIS. Regarding ecological flow rates (**Annex 17**), cultural heritage (**Annex 14**) and the management of summer grazing areas (**Annex 6**).

Remark N° 69 Future of the Works

In particular, the EIS should indicate what will be the fate of the tunnel and abstraction intakes after the 20 year lifespan of the Project has ended, this being the maximum reasonable time frame in view of the decline shown in the region - as can be verified in the abandonment of a number of lines (verify with Andacor and others). The EIS presents no reference to this situation or evaluation, showing a lack of rigor and concern for the future of the Project.

The Proyecto Hidroeléctrico Alto Maipo EIS should at the very least conduct all necessary studies at its own expense, over and above the general information contained in the EIS, presenting the results with proposals for the situation of replacing the Project's technologies with other systems that cause less damage to the physical and social environment. These conditions are required by communities in the area, and were specified and requested in a timely manner.

Thematic responses

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.01 Intakes

The Alto Maipo Hydroelectric Project (PHAM) plans to capture water resources at eight different points. The Project holds in-stream water rights at each of these points, and the concessions granting rights at most of these points include ecological flow rate stipulations issued by the Directorate General of Water (DGA).

The water intake points are as follows:

For the Alfalfal II Plant: the El Morado Stream, the La Engorda Stream, the Colina Stream, the Las Placas Creek, and the Yeso River. For the Las Lajas Plant: the Alfalfal Plant discharge, and the Colorado River at the Maitenes Intake. For a detailed description of planned installations, see Chapter 2, Section 2.2.2 of the EIS, and attached Annexes 1 and 8.

See Annex 12 of the EIS for a map of intakes in the PHAM area of influence. See Table 2.2.2, in Chapter 2 of the EIS, for the characteristics and descriptions of the intake installation.

For information on the Project's impact on water quality in the area's watercourses arising as a result of the construction of intakes, see Section I, Question 3 in the Addendum.

For the intake maintenance plan, the Chapter 2, Section 2.2.2 of the EIS, and additional information provided in Section I, Question 11 of the Addendum.

For clarifications regarding the El Yeso Reservoir, see Section I, question 27 in the Addendum.

For details on the construction methods and the mitigation and compensation measures planned by the Project to address the environmental impact of the intakes, see Annex 6 of the

Addendum.

PRO.03.02 Tunnels

The majority of the Project is planned for installation underground. The general characteristics of the tunnels are described in Chapter 2 of the EIS, Table 2.2.5 (for detailed geological information on the path taken by the tunnels, see Annex 46 of the EIS).

For an evaluation of the impact and environmental management measures associated with underground installations, see Chapter 6 of the EIS.

Annex 45 of the EIS, Hydro-Geology of Underground Works, presents a general description of the geological conditions that are expected to be found along the lengths of the tunnels; expected permeability based on geological knowledge and hydro-geological conditions in the area, incorporating experience gained during the construction of tunnels for the Alfalfa Plant, which has been operative for more than 17 years; as well as a description that includes the design of the tunnels, providing a brief explanation of the methods to be used to reduce and control water seepage.

With regard to the impact of the path taken by the tunnel passing underneath the El Morado Natural Monument, and measures to be taken to respect the area, see Section I, Responses 4, 5, and 6, in the Addendum.

Remark N° 70 Intakes - Visual Impact

The site where the intakes are to be installed in the tributaries of the Volcán River is widely visited in winter and in summer, with over 20 thousand Chileans and foreign nationals visiting each year to marvel at the area's scenic beauty.

In view of this situation, the visual impact of the channels and intakes that draw water into the tunnels should be established.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit

the more remote parts of the Project area, reducing

- emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism Scenery**

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

TUR.03 Visual impact

The Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and continue throughout the working life of the Project. A qualitative methodology is used to study these effects, whereby the first phase consists of identifying sources of visual Impact, and the second phase relates to identifying and classifying environmental impacts.

As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention.

As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access roads.

For further information on the methodology used for landscape impact assessment, see **Chapter 6, Section 6.1.4.10 of the EIS, and Annex 17 of Addendum 1.**

Remark N° 71 Muck Disposal Heaps

The sites where rock material produced through tunnel excavation will be disposed of in heaps should be specified definitively. In view of existing laws protecting the areas, these sites should not be located in the Cajón del Maipo Valley.

Thematic responses

MAR Muck

The PHAM plans to construct approximately 70 km of tunnels. The excavation of these tunnels will generate inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of inert material produced in road building and the construction of buried conduits.

This muck material will be deposited in the 14 muck disposal heaps that the Project plans to create. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria. For more information, please see **Annex 6 of the EIS** and **Annex 3 of the Addendum**.

MAR.01 Regulations

The Project Owner has made available a Management Plan for "Project Muck Disposal Heaps", which contains information on the technical, environmental, and safety specifications of the heaps, as well as recommendations contained in the Ministry of Public Works' 2004 Environmental Management Plan Manual for Works Subject to Concessions. In particular, the Plan establishes the environmental considerations adopted for the operation of the muck disposal heaps, to be implemented during the construction of tunnels and roads under the PHAM.

In order to comply with the environmental management measures contained in the EIS, an Environmental Monitoring Program will be conducted, with the aim of verifying the effectiveness of these measures and compliance with them. For details on the principal actions included in the Monitoring Program, and for the various stages of functionality of the muck disposal sites, see **Annex 6 of the EIS** and **Annex 3 of Addendum 1**.

For more information on the specific regulations applicable to the Project, and compliance therewith, see **Chapter 3 of the EIS**.

MAR.02 Location

The PHAM calls for the creation of 14 muck disposal heaps, for the disposal of waste material from tunnel boring and smaller quantities of inert waste from the construction of roads and buried conduits. Maps of the muck disposal heaps, and a copy of the muck disposal heap management plan, are included in Annex 6 of the Project EIS.

For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria.

From a technical and safety perspective, the muck disposal heap sites have been located as close as possible to exit points from tunnels and to surface work sites, in areas not at risk to landslides or landslip events.

The following aspects have been taken into account as environmental criteria in site selection:

Sites have been selected that are distant from any settlements or any housing used on a permanent or temporary basis.

Priority has been given to selecting sites with low visual impact - that is, in areas that are distant from potential observation points on public highways or high ground.

In the Project area's higher elevation regions, the disposal heaps have been sited up against natural topological features, such that the emplacement of the heaps' layers forms a continuation of the general landform structures of the area.

In general these are areas that are of low value as a habitat for plant life (soils with usage capacity ratings V, VI, and VII), and efforts have been made to avoid modifications to the original land form structures present or to surface watercourses.

Surface surveys have been conducted in all of these regions, as details in **Section 5.8, in Chapter 5 of the EIS**, to rule out the presence of sites of archeological and/or paleontological value at the muck disposal heap sites.

For more information, see **Annex 6 of the EIS** and **Annex 3 of Addendum 1**.

MAR.03 Characteristics

The material to be deposited in the muck disposal heaps will be inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of waste material produced in road building and the construction of buried conduits. It is expected that a total of 1.7 m cubic meters of TBM muck will be produced.

The total volume of material to be disposed of is estimated at 2.7 m cubic meters, including uncompacted rock and soil; this material will be disposed of at the 14 muck disposal heap sites planned under the PHAM. Maps of the muck disposal heaps, and a copy of the muck disposal heap management plan, are included in Annex 6 of the EIS.

The waste material produced through tunnel excavation, road building, and construction of buried

conduits during the construction phase will be deposited in a series of layers forming terraces. The muck disposal heaps will be built up in an organized manner, forming level and safe

platforms, with slopes at the sides with the natural gradient formed by the material in question, thus ensuring stability and permitting adequate drainage. All of these design features are in conformity with the muck disposal heap construction method and environmental measures indicated in **Section 4.2 of Annex 6 of the EIS, and Annex 3 of Addendum 1**.

Finally, the filling will be covered with 20 cm of organic soil, permitting the definitive finishing of the spoil heap.

Management and restoration techniques for the 14 muck disposal heaps are indicated in Annex 29, "Restoration Plan", which includes information on surface treatments.

MAR.04 Impact

All of the measures adopted for the creation, operation, and abandonment of the muck disposal heaps will be implemented by the Works Contractor. Gener will undertake an environmental monitoring plan addressing the management and usage of the sites, which will include site inspections and periodic review of site entry records.

Rainwater will be managed using specially designed channeling works, the details of each of which are indicated in the plans attached in Annex 6 of the EIS.

The Project Owner's reiterates its commitment to undertake an exhaustive program to rescue low mobility fauna in the area of direct influence of PHAM works (including the area to be occupied by the 14 sites where muck, spoil, and earth will be disposed of in heaps). This wildlife rescue will require the application of capture techniques suitable for small mammals, reptiles, and amphibians. **Annex 4 of Addendum 1** presents the Wildlife Rescue and Relocation Plan.

Even following surveys ruling out the presence of archeological or paleontological sites or finds in the muck disposal heap sites, the PHAM also includes a series of measures designed to prevent any intervention in sites with heritage value, with the implementation of restricted areas and training programs for contractor personnel. For more information, see **Annex 14 of Addendum 1 and Annex 33 of the EIS, "Restricted areas"**.

MAR.05 Composition and Hazardousness

Although the waste material produced from tunneling activities will be inert - in the construction of tunnels for the Alfalfa Plant, where 35 km of tunnels were excavated, no evidence was found of material that could lead to acidic or basic drainage in contact with rainwater - the PHAM includes a management plan applicable to water that may be produced from contact between muck or waste rock and rainwater or snow. For further details, see Annex 6 of the EIS.

The Project Owner plans to take measurements to assess the possibility of acidic drainage at the muck disposal heap sites, as indicated in **Annex 6, Section 5 in the EIS and Response 10 in Section 9 of Addendum 1**. The actions will form part of the Environmental Monitoring Plan, and will be preventive rather than response actions.

Remark N° 72 Muck disposal heaps - Details

The final disposal of the muck and waste rock produced should be clearly specified, providing detailed information on each of the planned heaps, featuring figures, graphics, and photographs showing where each heap will be sited and explaining its final visual impact.

Thematic responses

MAR Muck

The PHAM plans to construct approximately 70 km of tunnels. The excavation of these tunnels will generate inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of inert material produced in road building and the construction of buried conduits.

This muck material will be deposited in the 14 muck disposal heaps that the Project plans to create. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria. For more information, please see **Annex 6 of the EIS** and **Annex 3 of the Addendum**.

MAR.02 Location

The PHAM calls for the creation of 14 muck disposal heaps, for the disposal of waste material from tunnel boring and smaller quantities of inert waste from the construction of roads and buried conduits. Maps of the muck disposal heaps, and a copy of the muck disposal heap management plan, are included in Annex 6 of the Project EIS.

For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria.

From a technical and safety perspective, the muck disposal heap sites have been located as close as possible to exit points from tunnels and to surface work sites, in areas not at risk to landslides or landslip events.

The following aspects have been taken into account as environmental criteria in site selection:

Sites have been selected that are distant from any settlements or any housing used on a permanent or temporary basis.

Priority has been given to selecting sites with low visual impact - that is, in areas that are distant from potential observation points on public highways or high ground.

In the Project area's higher elevation regions, the disposal heaps have been sited up against natural topological features, such that the emplacement of the heaps' layers forms a continuation of the general landform structures of the area.

In general these are areas that are of low value as a habitat for plant life (soils with usage capacity ratings V, VI, and VII), and efforts have been made to avoid modifications to the original land form structures present or to surface watercourses.

Surface surveys have been conducted in all of these regions, as details in **Section 5.8, in Chapter 5 of the EIS**, to rule out the presence of sites of archeological and/or paleontological value at the muck disposal heap sites.

For more information, see **Annex 6 of the EIS** and **Annex 3 of Addendum 1**.

Remark N° 73 Muck disposal heaps - Capacity

The capacity of each muck disposal heap, and the source, composition, and quantity of material to be deposited in it, should be specified. The muck disposal heaps shown in the diagrams do not seem to be sufficient to receive the quantity of muck that will be generated, estimated at 1,400,000 m³.

Thematic responses

MAR Muck

The PHAM plans to construct approximately 70 km of tunnels. The excavation of these tunnels will generate inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of inert material produced in road building and the construction of buried conduits.

This muck material will be deposited in the 14 muck disposal heaps that the Project plans to create. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria. For more information, please see **Annex 6 of the EIS** and **Annex 3 of the Addendum**.

MAR.03 Characteristics

The material to be deposited in the muck disposal heaps will be inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of waste material produced in road building and the construction of buried conduits. It is expected that a total of 1.7 m cubic meters of TBM muck will be produced.

The total volume of material to be disposed of is estimated at 2.7 m cubic meters, including uncompacted rock and soil; this material will be disposed of at the 14 muck disposal heap sites planned under the PHAM. Maps of the muck disposal heaps, and a copy of the muck disposal heap management plan, are included in Annex 6 of the EIS.

The waste material produced through tunnel excavation, road building, and construction of buried conduits during the construction phase will be deposited in a series of layers forming terraces. The muck disposal heaps will be built up in an organized manner, forming level and safe platforms, with slopes at the sides with the natural gradient formed by the material in question, thus ensuring stability and permitting adequate drainage. All of these design features are in conformity with the muck disposal heap construction method and environmental measures indicated in **Section 4.2 of Annex 6 of the EIS, and Annex 3 of Addendum 1**.

Finally, the filling will be covered with 20 cm of organic soil, permitting the definitive finishing of the spoil heap.

Management and restoration techniques for the 14 muck disposal heaps are indicated in Annex 29, "Restoration Plan", which includes information on surface treatments.

MAR.05 Composition and Hazardousness

Although the waste material produced from tunneling activities will be inert - in the construction of tunnels for the Alfalfa Plant, where 35 km of tunnels were excavated, no evidence was found of material that could lead to acidic or basic drainage in contact with rainwater - the PHAM includes a management plan applicable to water that may be produced from contact between muck or waste rock and rainwater or snow. For further details, see Annex 6 of the EIS.

The Project Owner plans to take measurements to assess the possibility of acidic drainage at the muck disposal heap sites, as indicated in **Annex 6, Section 5 in the EIS** and **Response 10 in Section 9 of Addendum 1**. The actions will form part of the Environmental Monitoring Plan, and will be preventive rather than response actions.

Remark N° 74 Muck disposal heaps - Access

Additionally, if the muck disposal heaps are located in areas of scenic or tourism interest, access conditions during the construction period must be specifically stated.

The current situation - free access with no requirement to request authorizations, no barriers, and no guards requesting identification - should not be altered.

Thematic responses

MAR Muck

The PHAM plans to construct approximately 70 km of tunnels. The excavation of these tunnels will generate inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of inert material produced in road building and the construction of buried conduits.

This muck material will be deposited in the 14 muck disposal heaps that the Project plans to create. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria. For more information, please see **Annex 6 of the EIS** and **Annex 3 of the Addendum**.

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1**. The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS**.

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfal, Aucayes, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions.

The Project's has been designed and engineered to include a suite of measures for the optimization of the construction of new roads; for further information on these measures, see **Chapter 2, point 2.3.2.5 of the EIS**.

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in these areas, demonstrating that no interference will arise, due mainly to the following considerations:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

VIA.05 Free transit

The PHAM shall not interrupt access by mountain climbers, hikers, or permanent or sporadic

visitors who enter the area for leisure, sports, cultural activities, etc. For safety reasons, the PHAM will restrict access only to its installations and work sites. Similarly, there will be no restrictions on access to properties owned by third parties and used for livestock grazing; in other words, usage conditions in summer and winter grazing areas have always been subject to agreements between livestock herders and landowners, and this situation will not be modified by the Project.

Remark N° 75 Muck disposal heaps - Visual Impact

In Chapter 2, page 10, it is stated that the muck disposal heap sites constitute land that will be occupied on a permanent basis.

In order to prevent the generation of a major visual impact and heavy metal contamination that could leach into the environment from tunneling works, these sites should be restored once construction has been completed, and material deposited at an authorized site.

Thematic responses

MAR Muck

The PHAM plans to construct approximately 70 km of tunnels. The excavation of these tunnels will generate inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of inert material produced in road building and the construction of buried conduits.

This muck material will be deposited in the 14 muck disposal heaps that the Project plans to create. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria. For more information, please see **Annex 6 of the EIS** and **Annex 3 of the Addendum**.

MAR.01 Regulations

The Project Owner has made available a Management Plan for "Project Muck Disposal Heaps", which contains information on the technical, environmental, and safety specifications of the heaps, as well as recommendations contained in the Ministry of Public Works' 2004 Environmental Management Plan Manual for Works Subject to Concessions. In particular, the Plan establishes the environmental considerations adopted for the operation of the muck disposal heaps, to be implemented during the construction of tunnels and roads under the PHAM.

In order to comply with the environmental management measures contained in the EIS, an Environmental Monitoring Program will be conducted, with the aim of verifying the effectiveness of these measures and compliance with them. For details on the principal actions included in the Monitoring Program, and for the various stages of functionality of the muck disposal sites, see **Annex 6 of the EIS** and **Annex 3 of Addendum 1**.

For more information on the specific regulations applicable to the Project, and compliance therewith, see **Chapter 3 of the EIS**.

MAR.04 Impact

All of the measures adopted for the creation, operation, and abandonment of the muck disposal heaps will be implemented by the Works Contractor. Gener will undertake an environmental monitoring plan addressing the management and usage of the sites, which will include site inspections and periodic review of site entry records.

Rainwater will be managed using specially designed channeling works, the details of each of which are indicated in the plans attached in Annex 6 of the EIS.

The Project Owner's reiterates its commitment to undertake an exhaustive program to rescue low mobility fauna in the area of direct influence of PHAM works (including the area to be occupied by the 14 sites where muck, spoil, and earth will be disposed of in heaps). This wildlife rescue will require the application of capture techniques suitable for small mammals, reptiles, and amphibians. **Annex 4 of Addendum 1** presents the Wildlife Rescue and Relocation Plan.

Even following surveys ruling out the presence of archeological or paleontological sites or finds in the muck disposal heap sites, the PHAM also includes a series of measures designed to prevent any intervention in sites with heritage value, with the implementation of restricted areas and training programs for contractor personnel. For more information, see **Annex 14 of Addendum 1 and Annex 33 of the EIS**, "Restricted areas".

MAR.05 Composition and Hazardousness

Although the waste material produced from tunneling activities will be inert - in the construction of tunnels for the Alfalfa Plant, where 35 km of tunnels were excavated, no evidence was found of material that could lead to acidic or basic drainage in contact with rainwater - the PHAM includes a management plan applicable to water that may be produced from contact between muck or waste rock and rainwater or snow. For further details, see Annex 6 of the EIS.

The Project Owner plans to take measurements to assess the possibility of acidic drainage at the muck disposal heap sites, as indicated in **Annex 6, Section 5 in the EIS** and **Response 10 in Section 9 of Addendum 1**. The actions will form part of the Environmental Monitoring Plan, and will be preventive rather than response actions.

Remark N° 76 Muck disposal heap - water pollution

The Environmental Impact Study should consider the risk that, during the springtime snow melt, runoff water may be contaminated with the minerals that may be present in the waste material deposited in the heaps. To date, no empirical knowledge exists regarding what minerals may be present.

Thematic responses

MAR Muck

The PHAM plans to construct approximately 70 km of tunnels. The excavation of these tunnels will generate inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of inert material produced in road building and the construction of buried conduits.

This muck material will be deposited in the 14 muck disposal heaps that the Project plans to create. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria. For more information, please see **Annex 6 of the EIS** and **Annex 3 of the Addendum**.

MAR.04 Impact

All of the measures adopted for the creation, operation, and abandonment of the muck disposal heaps will be implemented by the Works Contractor. Gener will undertake an environmental monitoring plan addressing the management and usage of the sites, which will include site inspections and periodic review of site entry records.

Rainwater will be managed using specially designed channeling works, the details of each of which are indicated in the plans attached in Annex 6 of the EIS.

The Project Owner's reiterates its commitment to undertake an exhaustive program to rescue low mobility fauna in the area of direct influence of PHAM works (including the area to be occupied by the 14 sites where muck, spoil, and earth will be disposed of in heaps). This wildlife rescue will require the application of capture techniques suitable for small mammals, reptiles, and amphibians. **Annex 4 of Addendum 1** presents the Wildlife Rescue and Relocation Plan.

Even following surveys ruling out the presence of archeological or paleontological sites or finds in the muck disposal heap sites, the PHAM also includes a series of measures designed to prevent any intervention in sites with heritage value, with the implementation of restricted areas and training programs for contractor personnel. For more information, see **Annex 14 of Addendum 1 and Annex 33 of the EIS**, "Restricted areas".

MAR.05 Composition and Hazardousness

Although the waste material produced from tunneling activities will be inert - in the construction of tunnels for the Alfalfa Plant, where 35 km of tunnels were excavated, no evidence was found of material that could lead to acidic or basic drainage in contact with rainwater - the PHAM includes a management plan applicable to water that may be produced from contact between muck or waste rock and rainwater or snow. For further details, see Annex 6 of the EIS.

The Project Owner plans to take measurements to assess the possibility of acidic drainage at the muck disposal heap sites, as indicated in **Annex 6, Section 5 in the EIS** and **Response 10 in Section 9 of Addendum 1**. The actions will form part of the Environmental Monitoring Plan, and will be preventive rather than response actions.

Remark N° 77 El Volcán - Visual Impact

In Chapter 2, page 39, it is stated that:

"Priority has been given to selecting sites with low visual impact - that is, in areas that are distant from potential observation points on public highways or high ground."

Figure 2.2.1.2 indicates that the muck disposal heap pertaining to the El Volcán will be located well within the Valle de las Arenas, in a site that is fully visible from the road to Baños Colina and from the hiking trail to Volcán San José and the Mesoncito Valley - all located at high elevations. A public track also passes through the area.

Thematic responses

MAR Muck

The PHAM plans to construct approximately 70 km of tunnels. The excavation of these tunnels will generate inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of inert material produced in road building and the construction of buried conduits.

This muck material will be deposited in the 14 muck disposal heaps that the Project plans to create. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria. For more information, please see **Annex 6 of the EIS** and **Annex 3 of the Addendum**.

MAR.02 Location

The PHAM calls for the creation of 14 muck disposal heaps, for the disposal of waste material from tunnel boring and smaller quantities of inert waste from the construction of roads and buried conduits. Maps of the muck disposal heaps, and a copy of the muck disposal heap management plan, are included in Annex 6 of the Project EIS.

For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria.

From a technical and safety perspective, the muck disposal heap sites have been located as close as possible to exit points from tunnels and to surface work sites, in areas not at risk to landslides or landslip events.

The following aspects have been taken into account as environmental criteria in site selection:

Sites have been selected that are distant from any settlements or any housing used on a permanent or temporary basis.

Priority has been given to selecting sites with low visual impact - that is, in areas that are distant from potential observation points on public highways or high ground.

In the Project area's higher elevation regions, the disposal heaps have been sited up against natural topological features, such that the emplacement of the heaps' layers forms a continuation of the general landform structures of the area.

In general these are areas that are of low value as a habitat for plant life (soils with usage capacity ratings V, VI, and VII), and efforts have been made to avoid modifications to the original land form structures present or to surface watercourses.

Surface surveys have been conducted in all of these regions, as details in **Section 5.8, in Chapter 5 of the EIS**, to rule out the presence of sites of archeological and/or paleontological value at the muck disposal heap sites.

For more information, see **Annex 6 of the EIS** and **Annex 3 of Addendum 1**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

TUR Tourism

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in

a modification in level of

natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.03 Visual impact

The Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and continue throughout the working life of the Project. A qualitative methodology is used to study these effects, whereby the first phase consists of identifying sources of visual impact, and the second phase relates to identifying and classifying environmental impacts.

As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention.

As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access roads.

For further information on the methodology used for landscape impact assessment, see **Chapter 6, Section 6.1.4.10 of the EIS, and Annex 17 of Addendum 1**.

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1**.

The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.05 Free transit

The PHAM shall not interrupt access by mountain climbers, hikers, or permanent or sporadic visitors who enter the area for leisure, sports, cultural activities, etc. For safety reasons, the PHAM will restrict access only to its installations and work sites.

Similarly, there will be no restrictions on access to properties owned by third parties and used for livestock grazing; in other words, usage conditions in summer and winter grazing areas have always been subject to agreements between livestock herders and landowners, and this situation will not be modified by the Project.

Remark N° 78 Tunnels - Visual Impact

The visual impact caused by the work sites for the different tunnels to be built should be clearly specified.

Thematic responses

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.02 Tunnels

The majority of the Project is planned for installation underground. The general characteristics of the tunnels are described in Chapter 2 of the EIS, Table 2.2.5 (for detailed geological information on the path taken by the tunnels, see Annex 46 of the EIS).

For an evaluation of the impact and environmental management measures associated with underground installations, see Chapter 6 of the EIS.

Annex 45 of the EIS, Hydro-Geology of Underground Works, presents a general description of the geological conditions that are expected to be found along the lengths of the tunnels; expected permeability based on geological knowledge and hydro-geological conditions in the area, incorporating experience gained during the construction of tunnels for the Alfalfal Plant, which has been operative for more than 17 years; as well as a description that includes the design of the tunnels, providing a brief explanation of the methods to be used to reduce and control water seepage.

With regard to the impact of the path taken by the tunnel passing underneath the El Morado Natural Monument, and measures to be taken to respect the area, see Section I, Responses 4, 5, and 6, in the Addendum.

PRO.03.03 Encampments and Works Installations

For details on the creation of encampments and works installations, please see Chapter 2, Section 2.3.2.4 in the EIS.

For information on PHAM encampment and work site approach routes, see EIS, Chapter 2, Table 2.1.2,

For information on regulations, see Chapter 3 of the EIS and Annex 33, General Operating Regulations for Encampments and Work Sites.

For information on the management of waste produced at work sites and encampments, see Annex 18 of the EIS, "Site Installation Waste Management Plan".

For information on the discharge of treated wastewater, see Response 26 in the Addendum.

For information on human consumption of water at encampments and works installations, see Chapter 2, Section 2.3.2.4, parts b and i.

For an assessments of the impact of the creation of encampments and works installations, monitoring methods,

and conditions, see Chapter 6 of the EIS.

TUR Tourism

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.03 Visual impact

The Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and continue throughout the working life of the Project. A qualitative methodology is used to study these effects, whereby the first phase consists of identifying sources of visual impact, and the second phase relates to identifying and classifying environmental impacts.

As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention.

As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access roads.

For further information on the methodology used for landscape impact assessment, see **Chapter 6, Section 6.1.4.10 of the EIS, and Annex 17 of Addendum 1**.

Remark N° 79 Human Environment

In Chapter 5, point 5.5.2.5, on Basic Social Welfare Aspects, Page 48 D, it is stated that:
"All settlements in the Project's area of influence possess access to the natural environment. Indeed, a significant proportion of them are located in areas that feature almost untouched surroundings, and local residents therefore have extensive access to natural areas.

Key components of the area's natural environment include its watercourses and their valleys, as well as its mountain ranges. Similarly, although the area's highway infrastructure does not show high levels of development and is strongly affected by prevailing weather conditions, existing routes permit access to areas where the natural environment may be enjoyed. Nonetheless, hiking trails are of significant importance in the area, given that, together with their associated tourism infrastructure, they provide rapid and well-informed access to the local area's natural sites".

Attention should be drawn to the fact that their status as untouched areas draws in many Chilean and foreign tourists who come in search of country areas for relaxation and leisure; these areas are normally visited by people who are tired of being surrounded by tourism installations, as so often occurs in Europe, for example, where many tourist sites feature the presence of large, modern installations. For instance, it is normal to see groups of tourists camping out beside the Laguna del Morado Lake, and ice-climbing in the glacier above it; this is also a starting point for hiking trips and attempts on a number of nearby mountaintops.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;

- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism**

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

TUR.03 Visual impact

The Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and continue throughout the working life of the Project. A qualitative methodology is used to study these effects, whereby the first phase consists of identifying sources of visual impact, and the second phase relates to identifying and classifying environmental impacts.

As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention.

As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access

roads. For further information on the methodology used for landscape impact assessment,

see **Chapter 6, Section 6.1.4.10 of the EIS, and Annex 17 of Addendum 1.**

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1.** The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS.**

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfal, Aucayas, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions. The Project's has been designed and engineered to include a suite of measures for the optimization of the construction of new roads; for further information on these measures, see **Chapter 2, point 2.3.2.5 of the EIS.**

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in these areas, demonstrating that no interference will arise, due mainly to the following considerations:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

VIA.05 Free transit

The PHAM shall not interrupt access by mountain climbers, hikers, or permanent or sporadic visitors who enter the area for leisure, sports, cultural activities, etc. For safety reasons, the PHAM will restrict access only to its installations and work sites. Similarly, there will be no restrictions on access to properties owned by third parties and used for livestock grazing; in other words, usage conditions in summer and winter grazing areas have always been subject to agreements between livestock herders and landowners, and this situation will not be modified by the Project.

Remark N° 80 Tourism and Access Routes

It should be specified that both AES Gener and its contractors shall not be authorized to prohibit access for the purpose of visiting any area located close to the Projects work sites and installations, whether the visitor seeks to engage in scientific, cultural, or educational activities, leisure, sports, tourism, onward travel to another point, farming, livestock herding, or any other purpose, applying to Chileans citizens and foreigners.

Equally, there should be no barriers or guards who request identification or any other document or authorization for such access.

AES Gener should also take responsibility for the safety of those who directly enter its installations.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative,

that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism Scenery**

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1**. The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS**.

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfal, Aucayes, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions. The Project's has been designed and engineered to include a suite of measures for the optimization of the construction of new roads; for further information on these measures,

see

Chapter 2, point 2.3.2.5 of the EIS.

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in these areas, demonstrating that no interference will arise, due mainly to the following considerations:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

VIA.05 Free transit

The PHAM shall not interrupt access by mountain climbers, hikers, or permanent or sporadic visitors who enter the area for leisure, sports, cultural activities, etc. For safety reasons, the PHAM will restrict access only to its installations and work sites. Similarly, there will be no restrictions on access to properties owned by third parties and used for livestock grazing; in other words, usage conditions in summer and winter grazing areas have always been subject to agreements between livestock herders and landowners, and this situation will not be modified by the Project.

Remark N° 81

Human Environment - Activities around the Volcán River

In Chapter 5, page 5.5, on the HUMAN ENVIRONMENT: On page 5 of the baseline study, it is indicated that: *"Volcán River Valley: The settlements of El Romeral, El Volcán, Baños Morales, and Lo Valdés are located in this valley. These settlements depend on mining activity. Tourism has shown gradual growth as an economic activity in the district, principally in the settlements of Baños Morales and Lo Valdés. This is an area that attracts persons from different socio-economic groups, and those with special interests, including lower-middle socio-economic groups in the Metropolitan Region - who visit the popular Baños de Colina and the thermal springs at Baños Morales - as well as special interest groups such as Chilean and foreign mountain climbers frequenting Lo Valdés and the El Morado Sanctuary."*

The EIS does not mention that the areas that are most frequently visited by mountain climbers and by Chilean and foreign hikers also include the Valle de las Arenas, Mesoncito, El Morado, the Valle de la Engorda en route to the San José Volcano, and the Valle del Marmolejo en route to the Marmolejo Peak (see information on foreign visitors held by Difrol). Similarly, it does not indicate that the areas that are most accessible and that show growing tourism activity are the following sites:

The area known as "Choriboulder" located in the Valle de las Arenas (at which site plans call for the installation of an encampment and a muck disposal heap). This area is one of the country's most significant climbing sites for bouldering, and a starting point for visitors en route to other areas such as the Valle del Mesoncito, Laguna del Morado, the peaks known as Unión, Punta Italia, Punta Chile, Yamakawa, Mesón Alto for its south-east wall, Loma Larga, and many others. Evening gatherings of the climbing and mountaineering community are also held periodically at this site. The Laguna del Morado Lake, also known as "San Rafael de los Pobres" due to its scenic beauty that is reminiscent of the San Rafael Glacier but that can be visited more cheaply and easily from Santiago. This lake is fed by meltwater from the imposing El Morado Glacier, and it is a much-frequented site by not only Chileans but also foreigners, due to its spectacular vistas and easy, free access. This site is used by a number of institutions - including the National Mountain School, university mountaineering courses, and several mountain sports clubs - to give ice climbing and glacier mountaineering courses. This lake is not to be confused with the smaller Morales Lake, located inside the El Morado Natural Monument.

Cerro Marmolejo, a mountain with its summit at 6110 masl, accessed along the Marmolejo Valley. This is a particularly significant site in world tourism, being the planet's most southerly mountain of over six thousand meters - a feature that leads to global renown. It is also a vital site for Chilean mountaineering, as it is the most accessible peak of over six thousand meters in Central Chile, that can be climbed without bureaucratic obstacles.

The area features a number of less-visited mountain sites that are nonetheless of equal importance for tourism, such as the aforementioned Valle del Mesoncito, the peaks of Rubilla, Unión, Morado, Mesón Alto, Arenas, Punta Italia, Punta Chile, Moai, Yamakawa, Loma Larga, and the San José Volcano, among others.

These areas have potential not only in terms of tourism, but also for education: they are currently often used for mountaineering courses, training in camping techniques, winter survival, and ice climbing, rock climbing, and mixed climbing, leveraging their rapid and easy access. A range of educational institutions also use the area for field trips in courses on subjects such as ecotourism and geology.

These areas are visited not only during the summer season but also in the winter, when their beauty is all the more imposing and when they are similarly a key site for mountaineering training. Many of those who visit the Cajón del Maipo come in search of these untouched areas, helping support the tourism sector and contributing to the local economy.

If the implementation of this Project is implemented, AES Gener must offer a binding agreement that access to these areas (and to other areas not mentioned above) must continue to be free and open, with no requirement for permits or similar, and with no barriers or guards who request identification.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the

PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism**

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected

to have no impact on tourism activities (see **Chapter 6.4 of the EIS**). Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:
Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1**. The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.05 Free transit

The PHAM shall not interrupt access by mountain climbers, hikers, or permanent or sporadic visitors who enter the area for leisure, sports, cultural activities, etc. For safety reasons, the PHAM will restrict access only to its installations and work sites. Similarly, there will be no restrictions on access to properties owned by third parties and used for livestock grazing; in other words, usage conditions in summer and winter grazing areas have always been subject to agreements between livestock herders and landowners, and this situation will not be modified by the Project.

Remark N° 82

Tourism

In Chapter 6, page 6, it is stated that:

"In general, the area shows growth in tourism development, leveraging its scenic qualities and natural attractions; this is in contrast to the presence of little tourism equipment and infrastructure, or associated services."

The Environmental Impact Study should take into account that this scarcity of tourism equipment and infrastructure is exactly the reason why many visitors choose to come to the area: this is its key strength, and the reason why many Chilean and foreign tourists select this area, because it is not marred by any type of infrastructure.

The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 83

Tourism

In Chapter 5, point 5.6.2.4, part B: It is indicated that:

"With regard to basic infrastructure, there is a paved road to El Alfalfal, which is in a good condition; the high mountain areas of the region are accessible only along a private road owned by GENER S.A. Tourism signage and road signage is not adequate, with signs in a poor state of repair and some areas lacking signage altogether; public transport into the region is lacking".

It should be made clear that the lack of tourism activity and infrastructure described above can be attributed to the difficulties placed on access to the area's mountainous regions; this access depends precisely on the owner of the road leading to the high mountains, AES Gener.

This situation should be mentioned in the study as background information, relating to the attitude that the Company may adopt in other areas.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social

Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1**. The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS**.

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfal, Aucayes, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions. The Project's has been designed and engineered to include a suite of measures for the optimization

of the construction of new roads; for further information on these measures, see

Chapter 2, point 2.3.2.5 of the EIS.

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in these areas, demonstrating that no interference will arise, due mainly to the following considerations:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

Remark N° 84 Tourism - Activities

In Chapter 5, section 5.6.2.4 part D. El Volcán - Baños Morales area, Page 68, the following points are specified regarding tourist activities in the area:

(1) Hiking and trekking, (2) Medium and high mountain climbing, (3) Rock climbing, (4) Horse riding, (5) Picnicking, (6) Rock hunting and archeological research, (7) Wildlife watching and appreciation of plant life (8) Use of thermal springs, and (9) Cycling.

Using this numbering system, it should also be indicated that all of these activities are also conducted in the following areas:

Valle de las Arenas: activities (1), (2), (3), (4), (6) and (7) and (9). This area receives visitors in both winter and summer seasons, and is a very important site for tourism in the area - at least as much so as the Valle de Lo Valdés, which is mentioned.

Valle del Mesoncito: activities (1), (2) and (3).

Valle del Morado (as far as Laguna del Morado and beyond): activities (1), (2), (3) and (4). A major site for these activities.

Valle de la Engorda and Valle del Marmolejo: principally activities (1),

(2) and (3). Valle de Colina.(1), (2), (3) and (8)

All of these areas attract Chilean and foreign visitors, even during the winter season, and it should also be made clear that the Valle del Marmolejo is a particularly significant site in world tourism, being the planet's most southerly mountain of over six thousand meters - a feature that leads to global renown.

AES Gener's EIS should be more rigorous in mentioning activities conducted in areas located close to planned site installations. For its part, the company should offer a binding agreement to preserve and respect current access conditions - free, open access with no need to request authorizations or to present documents, without barriers or guards requesting that visitors show their identification.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects

associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism Scenery**

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1**. The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.05 Free transit

Remarks and Responses

Remark N° 84 Page 3

The PHAM shall not interrupt access by mountain climbers, hikers, or permanent or sporadic visitors who enter the area for leisure, sports, cultural activities, etc. For safety reasons, the PHAM will restrict access only to its installations and work sites. Similarly, there will be no restrictions on access to properties owned by third parties and used for livestock grazing; in other words, usage conditions in summer and winter grazing areas have always been subject to agreements between livestock herders and landowners, and this situation will not be modified by the Project.

Remark N° 85

Legal - Tourism

In Chapter 6, page 3, it is stated that:

"6.3.2 Identification of Components Vulnerable to Impact

It should be pointed out that the area where the PHAM is to be installed features the following unique features, which have been granted particular emphasis in the evaluation conducted:

- Presence of officially protected areas.
- Presence of tourist activities at nearby sites.
- Presence of natural environments of conservation interest.
- Presence of areas of archeological interest at nearby sites."

The Environmental Impact Study should be expanded to include:

Presence of tourism and scientific activities in the areas planned for works installations and project usage.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

ARQ.03 Scientific research

The scientific and cultural importance of the paleontological resources present has been recognized by the PHAM Project Owner, leading to a practice of taking particular care in selecting locations of works sites and installations in the Alto Volcán area, so as to protect and prevent the deterioration of all recorded or known resources. At the same time, the Project Owner has taken on a commitment to enhance knowledge of the area before starting planned works, undertaking survey studies of the Alto Volcán area, in parallel with suitable protection for sites recorded in that zone, as well as any new finds that may be detected during the course of construction under the PHAM. These activities will contribute not only to the maintenance of the aforementioned resources, but shall also add to the recognition of the sites where they are found.

Thus, in the framework of procedures for the approval of the EIS, all available information on the most significant earth science materials and components has been compiled, as applicable to the PHAM area and surroundings, forming part of the country's non-renewable scientific/cultural heritage. Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of materials or components present.

For more information, see **Annex 14 of Addendum 1**.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plant (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict

management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased. The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **PRO.02 EIS Additional and Complementary Information**

In accordance with consultation procedures conducted by oversight services, further studies and information have been incorporated into Addendum 1, which complements existing information provided in the EIS. Regarding ecological flow rates (**Annex 17**), cultural heritage (**Annex 14**) and the management of summer grazing areas (**Annex 6**).

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 86

Access Restrictions - Tourism

The final two paragraphs of point 5.6.3, in Chapter 5, titled Conclusions, state that:

"..., first of all, the Colorado River Basin area features development of observation and hiking tourism, conducted in the middle and lower Colorado River Valley, limited by the lack of any tourism infrastructure in the area; access to the upper stretches of the watercourse is controlled by private interests, meaning that a typical tourist is unable to access sites located along the Upper Colorado River."

It should be made clear that these controlling "private interests" are the company AES Gener itself - this is useful background information, relating to the attitude that the Company may adopt in other areas.

"... In the third area, on the Yeso River, there is a noteworthy absolute lack of tourism infrastructure, resulting in a significant proportion of the area's tourism being informal and spontaneous; similarly, the area has no settlement that would serve as a "center" for the development of tourist activities, and yet the area is also

strongly limited by climate conditions, which at times lead to the closure of Route G-455."

It should be made clear in the EIS that one of the reasons for the nearly complete absence of tourism in the area is the fact that it is controlled by private interests - in this case, Aguas Andinas. This may set precedents regarding the control exercised by companies in the areas where they hold land, and the possible resulting danger to tourism in the area. This also causes a danger to health, as people find themselves with ever more limited opportunities to engage in physical or leisure activities in an untouched environment.

In the areas involved in the Project, assuming that it goes ahead, AES Gener should offer a binding agreement to preserve and respect current access conditions - free, open access with no need to request authorizations or to present documents, without barriers or guards requesting that visitors show their identification.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and

- access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism**

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1**. The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The

layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS**.

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfal, Aucayas, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions. The Project's has been designed and engineered to include a suite of measures for the optimization of the construction of new roads; for further information on these measures, see **Chapter 2, point 2.3.2.5 of the EIS**.

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in these areas, demonstrating that no interference will arise, due mainly to the following considerations:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

VIA.05 Free transit

The PHAM shall not interrupt access by mountain climbers, hikers, or permanent or sporadic visitors who enter the area for leisure, sports, cultural activities, etc. For safety reasons, the PHAM will restrict access only to its installations and work sites. Similarly, there will be no restrictions on access to properties owned by third parties and used for livestock grazing; in other words, usage conditions in summer and winter grazing areas have always been subject to agreements between livestock herders and landowners, and this situation will not be modified by the Project.

Remark N° 87

Scenic Value - Tourism

In Chapter 5, page 7, table 5.9.3.2, Visual quality and fragility, High River Landscape Unit Volcán, it is stated that:

With regard to Traditional Value, it should be indicated that, as well as the points mentioned, this is an area that is widely visited by Chileans and foreigners, courses in mountaineering, rock climbing, ice climbing, mixed climbing, and camping techniques; that is, the seasonal grazing activities mentioned in the EIS are not the only uses to which the area is put, as shown in the following web links (the product of a simple Google search) that demonstrate the truth behind this assertion:

http://www.andesmountain.cl/santiagotrekking/trekking_morado.html
<http://www.caucen.com/foros/viewtopic.php?pid=468>
http://www.escalando.cl/morado_kalkwand.htm (where some project works are to be sited)
<http://www.montaña.uchile.cl/foros/viewtopic.php?t=852>
<http://www.loscorrecaminos.cl/cabalqatas.htm>
http://www.elbruio.cl/estero_morado.htm
<http://www.elbruio.cl/union.htm>
<http://www.refuqiolovaldes.com/actividades.html#office>
<http://www.refuqiolovaldes.com/actividades.html#fandinism>
<http://www.refuqiolovaldes.com/actividades.html#trekking>

Would such a range of tourism services be available if there were merely a grazing area?

Furthermore, with regard to physical accessibility, the Environmental Impact Study should establish that the area in question is one of the few sectors of the high Andes that can still be freely accessed by anyone who wishes to visit it; additionally, as a result of its physical isolation it retains a high level of conservation, without any past need to restrict access to it with any kind of barrier or to require any paperwork for entry permits.

Thematic responses

TUR Tourism

VIA.02 Roads

In view of the inaccessibility of part of the Project area, plans call for the installation of a total of approximately 31 km of new roads by the Project Owner, which will be used to access the work sites and for the transport of personnel, machinery, equipment, supplies, and spare parts that the contractor may require at the encampments, works installations, and work sites. The layout of the new service roads is presented in **Figures 2.2.2 to 2.2.10 of the EIS**.

The Project Owner also plans to conserve and maintain existing routes in the PHAM area of influence: Route G-25 (El Volcán area) and Route G-455 as far as the El Yeso Reservoir. It should be pointed out that the aforementioned road improvement activities are detailed in Annex 19 of the EIS; however, for Routes G-25 and G-455 these actions are subject to modification because the Metropolitan Region Highways Department possesses an engineering study for the improvement of Route G-25 (from the El Yeso Bridge to El Volcán); this body will therefore reach a mutual agreement with GENER on the definitive actions to be undertaken, with the signing of an Agreement between the parties.

As indicated in **Section 2.3.2.5 of the EIS**, regarding machinery to be used in road maintenance, plans call for one water tanker truck per work area (El Volcán, El Yeso, Alfalfal, Aucayes, and Las Lajas), working only during the summer season.

See **Response 1.42 in the Addendum**, containing tables summarizing road conservation actions.

The Project's has been designed and engineered to include a suite of measures for the optimization of the construction of new roads; for further information on these measures, see **Chapter 2, point 2.3.2.5 of the EIS**.

With regard to potential impacts on tourism activities that could arise as a result of the Project's road construction activities, Annex 9 of the EIS contains a map, plotted at a suitable scale, showing the spatial linkages of sites of interest for tourism, archeology, and natural beauty in these areas, demonstrating that no interference will arise, due mainly to the following considerations:

- Most of the work sites are located in largely isolated areas.
- The PHAM Project Owner or contractor shall not block the access or movement of visitors or tourists.
- The PHAM's environmental management measures shall guarantee the protection of paleontological and archeological resources, and shall prevent any interference with tourism or leisure activities.

The Project is not expected to interfere with traditional livestock activities arising through Project traffic flow, road works, or the closure of access to certain high mountain areas. One specific exception to the above relates to works to be undertaken in the lower-lying areas of the La Engorda summer grazing area, where plans call for sequential intervention limited to the immediate surroundings of work sites, on a temporary basis. Annex 34, the "Project Area Ethnographic Study", presents detailed information on the routes and areas that are traditionally used, as well as the seasonality and conditions of usage.

Remarks and Responses

Remark N° 87 Page 2

The PHAM shall not interrupt access by mountain climbers, hikers, or permanent or sporadic visitors who enter the area for leisure, sports, cultural activities, etc. For safety reasons, the PHAM will restrict access only to its installations and work sites. Similarly, there will be no restrictions on access to properties owned by third parties and used for livestock grazing; in other words, usage conditions in summer and winter grazing areas have always been subject to agreements between livestock herders and landowners, and this situation will not be modified by the Project.

Remark N° 88

Social Impact - Mitigation

AES Gener's proposal for the promotion of tourism in the area consists of a leaflet and a website, which would be added to the many such materials already in existence for the area. This proposal shows the company's indifference and lack of concern for a fragile community that is by no means wealthy, while complying with the letter of the law defining "social benefit".

Considering the Project's real impact and the investment that it will imply (600 million dollars), this planned investment in publicity is clearly insufficient to provide grounding for the Project presented in terms of social benefit.

AES Gener should offer real, long term, sustainable improvements for the different communities in the area, such as:

- * Construction of sports areas, and their maintenance in the long term (throughout the operating life of the Project).
 - * Usage of muck disposal heap sites to create new recreation areas.
 - * Construction of installations to contribute to local tourism in the area.
 - * Wide-ranging training to support personal business ventures.
- * Supply of information to communities in advance of the fact and in a timely manner regarding potential changes in ways of life.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism**

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 89

Scenic Value and other issues

In Chapter 4, point 4.3.5, pages 21 and 22. In view of the statements made on these pages, and that on page 22

"IT IS CONCLUDED THAT THE PROJECT SHALL NOT GENERATE SIGNIFICANT ALTERATION TO THE LANDSCAPE VALUE OF THE AREA WHERE IT IS TO BE INSTALLED".

AES Gener should accept a binding commitment that the Project will permit the implementation of scientific, cultural, and educational activities, as well as leisure, sports, tourism, free passage, farming, livestock herding, and other actions, both by Chileans and by foreigners, as have traditionally been conducted before the Project's entry into the SEIA. The company should adopt an absolute commitment regarding protection of the area's cultural and scenic richness, and quality of life.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plant (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative,

that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

CAL.02 Education

A goal of the Maitenes Foundation relates to education for children and young people against the backdrop of the natural environment (for more information on the goals and achievements of the Foundation, see Annex 26 of the EIS).

Gener firmly believes that contributions to the technical and vocational education and training of young people must keep sight of real employment possibilities. Therefore, as a first initiative it has earmarked resources for an education improvement project in the district, which will contribute to establishing education management for the restructuring of the school curriculum and professional technical capacity building, taking into account the features needed to boost local employability. Based on information and recommendations from this study, Gener, acting through the Maitenes Foundation, will undertake a Capacity Building for Employability Program fundamentally oriented towards those whose family, social, or economic situation has barred them from completing their education and training, or acquiring the skills needed in order to find work.

CAL.03 Sports and leisure areas

In order to avoid the loss or modification of land usage patterns, changes in usage, or loss of income associated with potential reduction in perceptions of the value of the surrounding areas, in terms of the provision of leisure, tourism, education, and other related services, the Project has developed a suite of measures that aim to minimize its environmental impact, so as to preserve the features that lead to the high perception of value of the area among residents, visitors, and tourists. These measures include: installation of most works in underground settings, thus minimizing their visual impact; the preservation of ecological flow rates in rivers and streams; and revegetation and reforestation of affected areas.

Similarly, the Project has enacted a suite of further measures to minimize interference with traditional livestock industries, as well as tourism and mountain/river sports.

In this way, the Project has taken all steps necessary in order to mitigate impacts on the environment, which will allow the area to retain the characteristics that make it so attractive for open-air education, tourism, and leisure activities. This will allow the project to operate alongside existing activities conducted in this area.

A wide-ranging suite of monitoring activities will be implemented to verify the effectiveness of the environmental measures (for more information, see **Chapter 8 of the EIS**). In parallel, and in order to verify that the Project does not affect cultural land usage patterns, applicable indices will be included for monitoring under the Social Indicator Monitoring (SIM) program.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**.

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.03 Visual impact

The Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and continue throughout the working life of the Project. A qualitative and qualitative methodology is used to study these effects, whereby the first phase consists of identifying sources of visual impact, and the second phase relates to identifying and classifying environmental impacts. As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention. As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access roads. For further information on the methodology used for landscape impact assessment, see **Chapter 6, Section 6.1.4.10 of the EIS, and Annex 17 of Addendum 1.**

Remark N° 90 EIS Basis

It is vital that the EIS must be based on real plans for the Project, not on a basis, regulations, and layouts that could be developed and change in many different ways. In the final, defined physical project, this background information would certainly related to a materially different EIS. The environmental impact study of AES Gener should clearly express the details of the project itself, not general considerations.

Thematic responses

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.02 EIS Additional and Complementary Information

In accordance with consultation procedures conducted by oversight services, further studies and information have been incorporated into Addendum 1, which complements existing information provided in the EIS. Regarding ecological flow rates (**Annex 17**), cultural heritage (**Annex 14**) and the management of summer grazing areas (**Annex 6**).

Remark N° 91 Construction Waste

In Chapter 4, point 4.3.1, page 4, construction waste.

It is indicated that these materials will be stored on a temporary basis in specially prepared sites, awaiting reuse or sale. However, the plan does not establish the length of the maximum waiting period or what will happen if this time period is exceeded, if items fail to be reused or sold. They could remain in the Andean valleys forever, affecting the health of persons and the environment, with knock on effects on tourism in areas where this occurs.

The Project Owner should agree to remove these materials within a time period no longer than six months from the end of the construction phase.

It should be made explicitly clear that AES Gener shall be directly responsible for the suitable removal of waste generated at the Project's encampments and site installations, even when these activities are conducted by contractors.

The Project Owner should specify what will be the fate of the encampments and site installations once the construction of the Project's tunnels and conduits has been completed.

AES Gener should agree to leave the surroundings as it found them before starting the EIS.

Thematic responses

RES Waste

The Project Owner indicates that most waste generated will be produced during the Project's construction phase. Two types of waste will be produced:

- **Solid waste:**
Construction waste such as wood, piping offcuts, rubble, wires, waste packaging, metals, etc.
Domestic waste or waste similar to domestic waste; plant waste such as remains of shrubs, weeds, and smaller quantities of tree waste removed from work sites.
- **Liquid waste:**
Applicable to the following activities: concrete production, washing and preparation of aggregates, and washing of truck chassis and load beds, machinery, and tools. Other liquid waste relates to wastewater from bathrooms, showers, canteens, and other activities conducted within encampments and site installations.

Gener will place strict contractual requirements on Contractors during the construction phase, aiming to ensure suitable management and final disposal of waste. Additionally, contractors and subcontractors shall agree to comply with regulations and oversight actions established by Law, to be applied to all works of this nature. The planned environmental management manual will prevent the occurrence of any pollution events linked to the Project (**see EIS, Annex 18**).

RES.01 Regulations and Responsibilities

In order to ensure the efficient, safe, and responsible treatment and management of waste matter generated by the PHAM an additional plan has been developed, the "Waste Management Plan for Work Sites, Works Installations, and Encampments", describing the procedures and equipment necessary for the management and disposal of waste produced during the construction of the Project, and which also specifies the responsibilities required under its implementation, what records must be kept, and what reports must be prepared for the purposes of control and oversight (Annex 18 of the EIS).

Gener will enforce implementation and compliance with the Project's environmental measures during construction management, placing strict contractual requirements on Contractors with the aim of ensuring suitable management and final disposal of waste. **RES.02 Location**

a) Handling of solid waste

Infrastructure for the integrated management of solid waste throughout the life of the Project, addressing the full gamut of temporary storage, preparation, and classification for transport, will comprise: waste collection and storage sites at the point where it is generated; areas for non-hazardous waste; and an area for hazardous waste. These waste storage areas, for non-hazardous and hazardous waste, will be located as shown in tables 5.1.1 (pages 7 and 8) and 5.3.1 (pages 11 and 12) in Annex 18 of the EIS, respectively.

Domestic waste and organic waste similar to domestic waste will be disposed of in a sanitary landfill site, while construction waste other than rubble and domestic waste or organic waste similar to domestic waste will be sent to the waste management area for classification, where materials with potential residual value will be returned for reuse or recycling, and the remainder will be dispatched to a sanitary landfill site (Annex 18 of the EIS, page 6).

b) Handling of liquid waste

● Wastewater

Wastewater produced in encampments will be subject to primary and secondary treatment, provided by installing modular activated sludge treatment plants at each encampment. These systems are based on unitary operations, with units designed and equipped to treat wastewater input such as to attain a level of purity sufficient for discharge or reuse with no associated risks to persons or to the environment, in full compliance with the regulations stipulated in Supreme Decree 1-90.

Wastewater generated at work areas, through the use of chemical bathrooms, will be transported to by the contractor in wastewater transport trucks to authorized sites for subsequent treatment.

Sludge generated through wastewater treatment will be removed by the works contractor for transport and disposal at authorized sites on a weekly basis. The sludge will be removed in wastewater transport trucks, and in accordance with the volume of sludge

produced it is expected that each encampment will require 2 to 3 journeys by 6 m³ capacity wastewater transport trucks per week, throughout the construction phase. Meanwhile, during the operations phase, the project will use the existing installations at the existing Alfalfa Plant Control Room, with no requirement to install a new wastewater treatment system, and thus not producing the sludge that such a system would generate.

For more information, see **Annex 18 of the EIS**.

- **Liquid industrial waste**

In view of the characteristics of this type of wastewater, the project plans to install a sequential sedimentation system. In view of this situation, a settling pond will be installed at each work site to permit the separation of liquid industrial waste into clear water and settleable sludge.

(see **Annex 5 of Addendum 1**)

RES.03 Characteristics

The types of waste to be produced during the construction phase, and the characteristics thereof, are as follows:

Characteristics of solid waste

Solid non-hazardous waste

This class of waste includes:

- Construction waste: consisting of wood, piping offcuts, rubble, wires, waste packaging, metals, empty cans and drums used to transport paint and adhesives, and other similar items.
- Domestic waste and other waste similar to domestic waste: basically includes leftover food from canteens, packaging, paper, card, and similar materials.
- Plant waste: consisting of remains of shrubs, weeds, and smaller quantities of tree waste removed from work sites.

Hazardous solid waste

Types of hazardous waste produced by the Project correspond to waste generated in workshops, storage areas, and work sites, such as:

- Solvents
- Oil waste
- Lubricating grease
- Batteries
- Oil filters

Characteristics of liquid waste

Wastewater

This class of liquid waste relates to wastewater from bathrooms, showers, canteens, and other activities conducted within encampments, site installations, and work sites. This wastewater will be subject to primary and secondary treatment, provided by installing modular activated sludge wastewater treatment plants at each encampment.

Liquid industrial waste

Liquid industrial waste shall be generated only through the following activities: concrete production, washing and preparation of aggregates, and washing of truck chassis and load beds, machinery, and tools.

As a result of this fact, this type of liquid waste shall be generated only at work sites.

Meanwhile, wastewater shall not be produced at the Project's encampments, as these areas shall be used only for personnel lodgings.

For more information, see **Annex 18 of the EIS**.

RES.04 Impact

Gener considers the suitable handling of waste produced by the Project to be of particular importance, and to this end it has designed rigorous programs for the handling, collection and storage, transport, and final disposal, reuse or sale of the different forms of waste that shall be generated at the Project's encampments and site installations, as well as its work sites. These programs have been designed specifically taking into account the particular features of the area where the Project is to be implemented, as well as regulations in force and the requirements imposed by the authorities during the Project's environmental evaluation. In general this category includes non-hazardous waste produced during construction activities and from domestic sources (the latter at workers' encampments), and production of this waste will cease at the end of the construction phase:

- Liquid waste will be reused or disposed of in compliance with applicable sector regulations. All discharge of treated wastewater will be conducted at isolated points, generally without the presence of other human use and with low physical and visual accessibility.
- For both hazardous and non-hazardous waste, the Project Owner plans to transport material for disposal in authorized sites, eliminating the possibility of creating centers of soil or water contamination that might have a negative effect on the quality of the area's scenery. The storage areas, rubble, and other materials stored on a temporary basis within site installations shall be removed once construction activities have been completed, and therefore shall have no impact on the landscape.

SLD Health Impact

The Project owner shall take responsibility for ensuring compliance with health and safety regulations, in order to prevent any possible risk to health and physical integrity for the inhabitants of San José Maipo as well as the persons working on the Project.

SLD.02.01 Pollutants

The Project's atmospheric emissions will correspond to dust suspended in the air as a result of earth moving activities (during excavations, loading and unloading, etc.), and the movement of vehicles at surface work areas. Emissions control will be conducted by means of:

- conservation of existing roads currently used by mine trucks,
- all new roads built will be treated with bischofite. Additional information provided in Section I, Question 42 and Section VI, Question 17, in the Addendum.
- use of tarpaulins covering truck loads,
- timely mechanical maintenance of equipment, machinery, and vehicles, and wetting of dusty surfaces
- use of wagons and belt conveyors for the removal of muck from within tunnels, and similar.

The Project Owner has conducted three studies to estimate emissions, which are included

in Annexes 4 and 5 of the EIS. These studies describe the analysis of estimates of atmospheric emissions caused by the PHAM, as well as the Emissions Compensation Program. The study identifies the Project activities that generate emission, quantifies the amount of emissions thus produced, estimates the quantity of emissions for each pollutant during each year of the construction phase, and, finally, develops the Project's emissions compensation program.

Remark N° 92 EIS for connection to the SIC Central Grid

The AES Gener environmental impact study does not specify how the electricity generated will be supplied to the SIC Central Electricity Grid. AES Gener should include full information regarding this sub-project in the EIS, as it is one of the units that make up the PHAM, given the fundamental linkage between the two projects. The same applies with regard to the concession to build and operate the hydroelectric plants, which should also be considered an integral part of this project, and which concession is currently not held by AES Gener.

This remark is presented with the concrete aim of preventing the authorization of one of these projects from implying a superficial examination of the others, in the sense that, if one of these projects is approved, the next will become a matter of "business necessity" for the Project Owner. Conversely, if the EIS addresses the activities of tunneling, water abstraction, power generation, and electricity distribution as a single unit, this will permit an enhanced perspective to be gained regarding the impact of the Project as a whole, such that all of its effects may be correctly evaluated.

Thematic responses

ELE Electrical Installations

The electrical installations presented in the EIS comprise the substation, to be located in the El Sauce area, the characteristics of which are to be found in **Annex 27 of the EIS**; given that the electricity transport layout (cabling and towers) is to be presented to the Environmental Impact Assessment System once all background information is available.

ELE.03 Transmission lines

In view of the project's location, close to Santiago, it is expected that the distance covered by the definitive cabling layout will be short, involving a minimum of sectors not subject to prior intervention. With regard to the specific location of the cabling layout, plans call for the use of the existing high tension power line used by the Queltehue, Volcán, and Maitenes Plants.

Once the layout of the high tension power line has been defined, the Project Owner will submit this plan to the Environmental Impact Assessment System, in accordance with legislation in force. In line with the development of the Compliance Plan for environmental legislation applicable to the Project, the General Regulations applicable in this instance are indicated below:

Decree with Force of Law N°4, dated 05 February, 2007, setting forth the Recast, Coordinated, and Systematized Text of the General Law on Electrical Services.

The General Law on Electrical Services governs the generation, transmission, distribution, and regimen of concessions and tariffs applicable to electrical energy, and the functions of the State with regard to these areas.

Supreme Decree N° 327, Regulations Regarding the General Law on Electrical Services

The Regulations Regarding the General Law on Electrical Services establish, in their 8th Article, that hydroelectric power plants, electrical substations, and transmission lines may be installed without making a request for a concession, when the interested party wishes. These concessions may be provisional (in order to study projects) or definitive. A definitive concession is granted by a supreme decree issued by the Ministry of the Economy, by order of the President of the Republic. Permits relating to electrical installations that do not require concessions are granted by the corresponding Municipal Governments.

For further information and analysis on the aforementioned regulations, with regard to the Project, as well as in terms of general aspects, compliance, and regulatory bodies, please see **Sections 3.1.6 and 3.1.7 of Chapter 3 of the EIS**, where more detailed versions of this information can be found.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water

from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.01 Intakes

The Alto Maipo Hydroelectric Project (PHAM) plans to capture water resources at eight different points. The Project holds in-stream water rights at each of these points, and the concessions granting rights at most of these points include ecological flow rate stipulations issued by the Directorate General of Water (DGA).

The water intake points are as follows:

For the Alfalfal II Plant: the El Morado Stream, the La Engorda Stream, the Colina Stream, the Las Placas Creek, and the Yeso River. For the Las Lajas Plant: the Alfalfal Plant discharge, and the Colorado River at the Maitenes Intake. For a detailed description of planned installations, see Chapter 2, Section 2.2.2 of the EIS, and attached Annexes 1 and 8.

See Annex 12 of the EIS for a map of intakes in the PHAM area of influence. See Table 2.2.2, in Chapter 2 of the EIS, for the characteristics and descriptions of the intake installation.

For information on the Project's impact on water quality in the area's watercourses arising as a result of the construction of intakes, see Section I, Question 3 in the Addendum.

For the intake maintenance plan, the Chapter 2, Section 2.2.2 of the EIS, and additional information provided in Section I, Question 11 of the Addendum.

For clarifications regarding the El Yeso Reservoir, see Section I, question 27 in the Addendum.

For details on the construction methods and the mitigation and compensation measures planned by the Project to address the environmental impact of the intakes, see Annex 6 of the Addendum.

PRO.03.02 Tunnels

The majority of the Project is planned for installation underground. The general characteristics of the tunnels are described in Chapter 2 of the EIS, Table 2.2.5 (for detailed geological information on the path taken by the tunnels, see Annex 46 of the EIS).

For an evaluation of the impact and environmental management measures associated with underground installations, see Chapter 6 of the EIS.

Annex 45 of the EIS, Hydro-Geology of Underground Works, presents a general description of the geological conditions that are expected to be found along the lengths of the tunnels; expected permeability based on geological knowledge and hydro-geological conditions in the area, incorporating experience gained during the construction of tunnels for the Alfalfal Plant, which has been operative for more than 17 years; as well as a description that includes the design of the tunnels, providing a brief explanation of the methods to be used to reduce and control water seepage.

With regard to the impact of the path taken by the tunnel passing underneath the El Morado Natural Monument, and measures to be taken to respect the area, see Section I, Responses 4, 5, and 6, in the Addendum.

Remark N° 93

Flow rates - "Hanging" channels

A danger exists that a vast number of existing irrigation channels might be left "hanging" - that is, their intakes could be left at a higher level than the rivers that feed them, in view of reduced flow rates in these rivers. It is estimated that this problem could affect the irrigation of more than 500 hectares of agricultural land. AES Gener should conduct studies on a case by case basis to assess this situation, and these studies should be subject to approval by the Directorate General of Water (DGA). This will require the preparation and presentation of a map to be included in the EIS, showing all water intake works located within the Project's area of influence, as well as all natural watercourses subject to intervention.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds in-stream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in **Chapter 2 of the EIS**.

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that is, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**).

AGU.02.02 "Hanging" channels

Gener has repeatedly issued declarations that it is aware that not only the works that it shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

Remark N° 94 Noise Emissions

The Environmental Impact Study should take into account the fact that sources of noise located far from settlements may still affect tourism, and that many persons may cease to visit the areas where construction is to be conducted due to the noise and visual effects caused by a construction site of this nature. Harmful effects on local fauna will also occur.

The Environmental Impact Study should also address noise that may be generated by the construction Project's water conduits. Failure to take this point into account will result in many people losing part of their income derived from vehicle rental, transport, entry fees, sale of food, mule rental, horse rental, tourist guide services, etc.

AES Gener should clearly establish in the EIS what actions it will take to mitigate noise emission in areas located far from settlement, but of interest to tourism or frequented by wildlife.

Thematic responses

RSG Risk

The Project Owner possesses a general risk prevention strategy that imposes certain measures on the Project during its different stages of advance. This strategy features the following components:

- a) Measures incorporated into the Project's engineering design.
- b) Systematic verification of compliance with applicable regulations
- c) Establishment of restricted areas
 - c.1) Area restricted due to their archeological, paleontological, or heritage value
 - c.2) Area of natural value that requires protection by the Project
 - c.3) Officially protected area.
- d) Expert supervision during construction
- e) Training regarding environmentally sensitive issues
- f) Internal risk management and accident prevention programs
- g) Separation of works installations and encampments

For further information on each of these points, please see **Chapter 7 of the EIS**, which specifies the **Environmental Management Plan**, the **Risk Control and Prevention Plan** designed for the Project, the safety measures to be adopted in light of the risks identified, and, finally, the **Accident control plan**, to be activated in the event of the failure of the preventive measures taken by the Project Owner. Furthermore, **Annex 32 of the EIS** presents the **Risk and Contingency Prevention Plan** for contractors.

RSG.03 Blasting

Excavation methods using explosives will be used for the excavation of a proportion of the tunnels involved in the Project. Other tunnels will be excavated using a Tunnel Boring Machine, as described in **Section 2.3.2.2 the EIS**. The surface points where blasting will lead to perceptible effects are

located close to the entrances of the tunnels that are to be constructed using the traditional drill and blast excavation technique (**Section 6.4.1.2 and Section 6.4.1.3 of the EIS, and Section 6, Question 26 in the Addendum**). At surface locations in areas where tunnels are to be excavated using the traditional method, no vibrations will be caused that could lead to risks of landslides, rock falls, and landslips resulting from the construction of the tunnels, because these excavation techniques will be used at a great depth below the surface.

Noise from blasting will only be audible during the opening of the ends of the tunnels. Once inside the tunnels, excavation works (including detonations) will not be audible, and therefore will not constitute a significant source of noise, and audible blasting will therefore only occur while the ends of the tunnels are being excavated. It is estimated that there will be 2 or 3 detonations per day at each work site. Based on these

levels, added to the background noise in each area, it was determined that noise will not rise above the maximum level permitted under MINSEGPRES Supreme Decree 146/97. For more information on this topic, see **Section 6.4.1.2 of the EIS** and **Section 8.2.2 of the EIS**, which describe the noise and vibration monitoring program associated with the blasting activities, as established in **Section 6, Question 41 of the Addendum**.

It is important to point out that a controlled intervention will be completed in advance of blasting, consisting of the installation of work platforms, through the removal of vegetation and the rescue of individual plants and/or animals of conservation interest that present low mobility, limited populations, and endemism, and other characteristics of the project and the range of the species in question (see Annex 4 of the Addendum), in particular through the implementation of the "Wildlife Rescue and Relocation Plan".

Regarding the construction of the El Volcán Tunnel, located beneath the El Morado Monument, the depth of the tunnel will vary between 550 m and over 1500 m. No impacts are expected relating to vibrations reaching the El Morado Glacier. For more information, see **Addendum 1, Section 6, Response 13 and Section 1, responses 4, 5 and 6**.

With regard to safety measures planned applying to the handling and storage of explosives, specified in Annex 32 of the EIS, regulatory stipulations for risk prevention and emergency control are provided that will apply to all contracting of works and/or services by Gener, in compliance with the requirements set forth in Law 16,744, Article 66 part 2. See also **Addendum 1, Section 1, Question 35**.

SLD Health Impact

The Project owner shall take responsibility for ensuring compliance with health and safety regulations, in order to prevent any possible risk to health and physical integrity for the inhabitants of San José Maipo as well as the persons working on the Project.

SLD.03 Acoustic

In the field of Environmental Impact, specifically acoustic impact, the Project Owner has conducted a wide-ranging study to estimate acoustic emissions generated during the construction of the PHAM. For more information on the acoustic impact of the PHAM, and methodologies, modeling techniques, and actions to be taken to minimize such impact, please see **Annex 30 of the EIS** and **Section II, Question 8 in the Addendum**.

Plans for blasting activities, specifically including the frequency, quantity, timing, and work periods of blasting, will be determined on site in accordance with the characteristics of each works activity and work site. Works installation working days will be designated to prioritize the completion of surface works during the

daytime (8:00-21:00 hrs.); for blasting activities, plans call for an information program at the time of the activity, defining and clarifying the periods when noise-producing activities will take place, in order to integrate the community into efforts towards the completion of the Project. Another point worthy of emphasis is that the work sites (tunnel excavation, access windows, and entrances/exits) will not be sited close to settlements, thus preventing most of the potential acoustic impact that could be caused by the PHAM.

Wildlife rescue will be conducted through animal rescue activities based on the trapping of reptiles and amphibians before explosives are used, before service tracks are built, and before the modification of river flow.

Finally, and in order to comply with the requirements set forth above, the Project Owner shall be subject to:

1. Supreme Decree 146 (Establishing Standards on the Emission of Nuisance Noise Generated by Fixed Sources) establishing maximum permissible sound pressure levels, corrected according to technical criteria to evaluate and classify nuisance noises generated by fixed sources affecting the community, such as industrial, commercial, leisure, and artistic activities.
2. Exempt Decree 130 (Establishing restrictions on the movement of cargo trucks). The movement of trucks larger than 4 tons will be suspended from 14:00 hours on Saturdays through to midnight on each Sunday night on Route G-25 and Route G-421.

For more information on the acoustic impact of the PHAM, and regulations (Chapter 6 of the EIS), mitigation measures, methodologies, modeling techniques, and actions to be taken to minimize such impact, please see Annex 30 of the EIS, as mentioned above.

Finally, in order to verify the effectiveness of the mitigation measures taken, noise monitoring will be conducted at 8 sensitive points, following the procedure established in MINSEGPRES Supreme Decree 146/97, in order to verify compliance with the maximum permitted limits for sound pressure level (see details in **Chapter 8 of the EIS, Section 8.2.2**).

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. In parallel, the study investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 95 Noise

With reference to the information presented in Chapter 2, Page 56, an explanation should be provided as to what media will be used to indicate the times and dates of particularly noisy works activities.

If the implementation of the Project is authorized, AES Gener should refrain from generating noise of any kind during weekends and holidays, in both populated areas and zones of interest for tourism.

Thematic responses

RSG Risk

The Project Owner possesses a general risk prevention strategy that imposes certain measures on the Project during its different stages of advance. This strategy features the following components:

- a) Measures incorporated into the Project's engineering design.
- b) Systematic verification of compliance with applicable regulations
- c) Establishment of restricted areas
 - c.1) Area restricted due to their archeological, paleontological, or heritage value
 - c.2) Area of natural value that requires protection by the Project
 - c.3) Officially protected area.
- d) Expert supervision during construction
- e) Training regarding environmentally sensitive issues
- f) Internal risk management and accident prevention programs
- g) Separation of works installations and encampments

For further information on each of these points, please see **Chapter 7 of the EIS**, which specifies the **Environmental Management Plan**, the **Risk Control and Prevention Plan** designed for the Project, the safety measures to be adopted in light of the risks identified, and, finally, the **Accident control plan**, to be activated in the event of the failure of the preventive measures taken by the Project Owner. Furthermore, **Annex 32 of the EIS** presents the **Risk and Contingency Prevention Plan** for contractors.

RSG.03 Blasting

Excavation methods using explosives will be used for the excavation of a proportion of the tunnels involved in the Project. Other tunnels will be excavated using a Tunnel Boring Machine, as described in **Section 2.3.2.2 of the EIS**. The surface points where blasting will lead to perceptible effects are

located close to the entrances of the tunnels that are to be constructed using the traditional drill and blast excavation technique (**Section 6.4.1.2 and Section 6.4.1.3 of the EIS, and Section 6, Question 26 in the Addendum**). At surface locations in areas where tunnels are to be excavated using the traditional method, no vibrations will be caused that could lead to risks of landslides, rock falls, and landslips resulting from the construction of the tunnels, because these excavation techniques will be used at a great depth below the surface.

Noise from blasting will only be audible during the opening of the ends of the tunnels. Once inside the tunnels, excavation works (including detonations) will not be audible, and therefore will not constitute a significant source of noise, and audible blasting will therefore only occur while the ends of the tunnels are being excavated. It is estimated that there will be 2 or 3 detonations per day at each work site. Based on these

levels, added to the background noise in each area, it was determined that noise will not rise above the maximum levels permitted under MINSEGPRES Supreme Decree 146/97. For more information on this topic, see **Section 6.4.1.2 of the EIS** and **Section 8.2.2 of the EIS**, which describe the noise and vibration monitoring program associated with the blasting activities, as established in **Section 6, Question 41 of the Addendum**.

It is important to point out that a controlled intervention will be completed in advance of blasting, consisting of the installation of work platforms, through the removal of vegetation and the rescue of individual plants and/or animals of conservation interest that present low mobility, limited populations, and endemism, and other characteristics of the project and the range of the species in question (see Annex 4 of the Addendum), in particular through the implementation of the "Wildlife Rescue and Relocation Plan".

Regarding the construction of the El Volcán Tunnel, located beneath the El Morado Monument, the depth of the tunnel will vary between 550 m and over 1500 m. No impacts are expected relating to vibrations reaching the El Morado Glacier. For more information, see **Addendum 1, Section 6, Response 13 and Section 1, responses 4, 5 and 6**.

With regard to safety measures planned applying to the handling and storage of explosives, specified in Annex 32 of the EIS, regulatory stipulations for risk prevention and emergency control are provided that will apply to all contracting of works and/or services by Gener, in compliance with the requirements set forth in Law 16,744, Article 66 part 2. See also **Addendum 1, Section 1, Question 35**.

SLD Health Impact

The Project owner shall take responsibility for ensuring compliance with health and safety regulations, in order to prevent any possible risk to health and physical integrity for the inhabitants of San José Maipo as well as the persons working on the Project.

SLD.03 Acoustic

In the field of Environmental Impact, specifically acoustic impact, the Project Owner has conducted a wide-ranging study to estimate acoustic emissions generated during the construction of the PHAM. For more information on the acoustic impact of the PHAM, and methodologies, modeling techniques, and actions to be taken to minimize such impact, please see **Annex 30 of the EIS** and **Section II, Question 8 in the Addendum**.

Plans for blasting activities, specifically including the frequency, quantity, timing, and work periods of blasting, will be determined on site in accordance with the characteristics of each works activity and work site. Regarding works activity scheduling, priority will be placed on completion of surface works during the daytime (8:00-21:00 hrs.); for blasting activities, plans call for an information program at the time of the activity, defining and clarifying the periods when noise-producing activities will take place, in order to integrate the community into efforts towards the completion of the Project.

Another point worthy of emphasis is that the work sites (tunnel excavation, access windows, and entrances/exits) will not be sited close to settlements, thus preventing most of the potential

acoustic impact that could be caused by the PHAM.

Wildlife rescue will be conducted through animal rescue activities based on the trapping of reptiles and amphibians before explosives are used, before service tracks are built, and before the modification of river flow.

Finally, and in order to comply with the requirements set forth above, the Project Owner shall be subject to:

1. Supreme Decree 146 (Establishing Standards on the Emission of Nuisance Noise Generated by Fixed Sources) establishing maximum permissible sound pressure levels, corrected according to technical criteria to evaluate and classify nuisance noises generated by fixed sources affecting the community, such as industrial, commercial, leisure, and artistic activities.
2. Exempt Decree 130 (Establishing restrictions on the movement of cargo trucks). The movement of trucks larger than 4 tons will be suspended from 14:00 hours on Saturdays through to midnight on each Sunday night on Route G-25 and Route G-421.

For more information on the acoustic impact of the PHAM, and regulations (Chapter 6 of the EIS), mitigation measures, methodologies, modeling techniques, and actions to be taken to minimize such impact, please see Annex 30 of the EIS, as mentioned above.

Finally, in order to verify the effectiveness of the mitigation measures taken, noise monitoring will be conducted at 8 sensitive points, following the procedure established in MINSEGPRES Supreme Decree 146/97, in order to verify compliance with the maximum permitted limits for sound pressure level (see details in **Chapter 8 of the EIS, Section 8.2.2**).

Remark N° 96 Blasting

The location, duration, quantity, and frequency of blasting should be specified for all sectors.

Thematic responses

RSG Risk

The Project Owner possesses a general risk prevention strategy that imposes certain measures on the Project during its different stages of advance. This strategy features the following components:

- a) Measures incorporated into the Project's engineering design.
- b) Systematic verification of compliance with applicable regulations
- c) Establishment of restricted areas
 - c.1) Area restricted due to their archeological, paleontological, or heritage value
 - c.2) Area of natural value that requires protection by the Project
 - c.3) Officially protected area.
- d) Expert supervision during construction
- e) Training regarding environmentally sensitive issues
- f) Internal risk management and accident prevention programs
- g) Separation of works installations and encampments

For further information on each of these points, please see **Chapter 7 of the EIS**, which specifies the **Environmental Management Plan**, the **Risk Control and Prevention Plan** designed for the Project, the safety measures to be adopted in light of the risks identified, and, finally, the **Accident control plan**, to be activated in the event of the failure of the preventive measures taken by the Project Owner. Furthermore, **Annex 32 of the EIS** presents the **Risk and Contingency Prevention Plan** for contractors.

RSG.03 Blasting

Excavation methods using explosives will be used for the excavation of a proportion of the tunnels involved in the Project. Other tunnels will be excavated using a Tunnel Boring Machine, as described in **Section 2.3.2.2 of the EIS**. The surface points where blasting will lead to perceptible effects are

located close to the entrances of the tunnels that are to be constructed using the traditional drill and blast excavation technique (**Section 6.4.1.2 and Section 6.4.1.3 of the EIS, and Section 6, Question 26 in the Addendum**). At surface locations in areas where tunnels are to be excavated using the traditional method, no vibrations will be caused that could lead to risks of landslides, rock falls, and landslips resulting from the construction of the tunnels, because these excavation techniques will be used at a great depth below the surface.

Noise from blasting will only be audible during the opening of the ends of the tunnels. Once inside the tunnels, excavation works (including detonations) will not be audible, and therefore will not constitute a significant source of noise, and audible blasting will therefore only occur while the ends of the tunnels are being excavated. It is estimated that there will be 2 or 3 detonations per day at each work site. Based on these

levels, added to the background noise in each area, it was determined that noise will not rise above the maximum levels permitted under MINSEGPRES Supreme Decree 146/97. For more information on this topic, see **Section 6.4.1.2 of the EIS** and **Section 8.2.2 of the EIS**, which describe the noise and vibration monitoring program associated with the blasting activities, as established in **Section 6, Question 41 of the Addendum**.

It is important to point out that a controlled intervention will be completed in advance of blasting, consisting of the installation of work platforms, through the removal of vegetation and the rescue of individual plants and/or animals of conservation interest that present low mobility, limited populations, and endemism, and other characteristics of the project and the range of the species in question (see Annex 4 of the Addendum), in particular through the implementation of the "Wildlife Rescue and Relocation Plan".

Regarding the construction of the El Volcán Tunnel, located beneath the El Morado Monument, the depth of the tunnel will vary between 550 m and over 1500 m. No impacts are expected relating to vibrations reaching the El Morado Glacier. For more information, see **Addendum 1, Section 6, Response 13 and Section 1, responses 4, 5 and 6**.

With regard to safety measures planned applying to the handling and storage of explosives, specified in Annex 32 of the EIS, regulatory stipulations for risk prevention and emergency control are provided that will apply to all contracting of works and/or services by Gener, in compliance with the requirements set forth in Law 16,744, Article 66 part 2. See also **Addendum 1, Section 1, Question 35**.

Remark N° 97

Labor Hiring

The Project Owner overestimates job creation, whereas the contractor and not the company itself shall be in charge of hiring. Gener should:

- * Quantify the amount of labor that it shall hire in the district.
- * Describe the positions to be filled.

* Establish a binding agreement between the Project Owner and the Municipal Government whereby Gener agrees to source 100% of the persons who have registered at the labor brokerage office.

Thematic responses

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

SOC.01.01 Requirements

In view of the characteristics and scale of the Project, personnel with specific qualifications will be required for the operation and maintenance of plant machinery and equipment, during the operations phase. Conversely, during the Project Construction Phase, it is projected that labor requirements will create jobs not only for mining workers, but also for machinery operators, drivers, and both skilled and unskilled construction personnel, the latter working mainly as day laborers and assistants.

The population of the Project's area of direct influence has been found to possess levels of training and specialization (occupation as defined under the CIIU code) that shall permit them to access both skilled and unskilled work positions created by the Project.

SOC.01.02 Working conditions

To date no schedule exists specifying labor requirements for the full duration of the construction phase. Detailed information specifying jobs created under average and peak labor requirements, broken down by labor requirement dynamics for each encampment, will only be available once the Project Owner has tendered the works contracts.

During the operations phase, it is expected that personnel requirements will amount to approximately 80 positions available, required for power plant operations and maintenance activities. Unlike work positions created during the construction phase, the jobs created in the operations phase will be permanent (EIS, Chapter 6, Section 6.4.2.4).

The Project Owner will provide for coordination between the construction works contractors, the Labor Brokerage Office, and the Municipality of San José de Maipo, regarding local labor required and jobs sought. The PHAM has accepted a commitment to incentivize works contractors to prioritize local contracting of labor required.

No prior training is planned in advance of the Construction Phase. However, such training will form part of the programs implemented in the more advanced phases of the project.

Remark N° 99 Supply Purchase Agreements

The Project Owner overestimates the benefit that will be generated for the community through the purchase of supplies and the presence of 20 encampments.

The Project Owner should enter into a binding agreement with the SJM Chamber of Commerce and Tourism, agreeing that all supplies required in the functioning of the encampments shall be acquired in the district.

Thematic responses

Specific response

The Project owner is not able to agree to this request because it goes against the concepts of free competition, and it is also unable to oblige contractors to purchase their supplies in the district.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social

Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment.

By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.05 Promoting entrepreneurship

The company has agreed to use its **Fundación Maitenes** foundation to set aside an **annual fund over a 10 year period starting in 2010**, to support local residents who formulate tourism development business plans for implementation in the area. These projects will be financed through funds open for competitive tenders; submissions will be evaluated on their own merit by a council of community representatives, which will select which projects will be funded. The initiative to be implemented by the Fundación Maitenes may be linked to projects in progress run by public institutions and services in the district, related to the two lines of action that the foundation has agreed to support. This linkage may help to strengthen state-run initiatives and foster sustainability over the course of time for the actions supported by the foundation, during the period in which the program is active.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district. In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district. During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. In parallel, the study investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 100**Irrigation** **User**
Communities

The Project Owner should attach written consent by the "El Manzano Channel" and "Maurino Channel"

Thematic responses

Specific response

The Project Owner reiterates its commitment to ensuring that necessary infrastructure exists in the river to permit water to enter the channels at all times, in accordance with the rights granted and the availability of the river throughout the life of the PHAM project.

In conformity with commitments made in meetings held with the management of the El Manzano Channel at the offices of Gener between January and October 2008, Gener has agreed to underwrite the construction of new infrastructure necessary in order to ensure water capture from the Colorado River to which that community possesses legally granted rights, as well as to pay all additional maintenance costs that the community may incur as a consequence of the operation of the PHAM. Furthermore, Gener will pay all additional costs payable by the community to the DGA for corresponding permit applications.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water**rights**

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in
Chapter 2 of the
EIS.

AGU.02.01**Irrigation**

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that it, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02
channels**"Hanging"**

shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

Remark N° 101 El Manzano EIS

The EIS presented by Gener does not include impact that will be generated by the PHAM at El Manzano.

* The EIS should include:

* Identification, prediction, interpretation, mitigation plan, and evaluation of the impact that will be caused, particularly with regard to irrigation systems.

Thematic responses

Specific response

The Project Owner reiterates its commitment to ensuring that necessary infrastructure exists in the river to permit water to enter the channels at all times, in accordance with the rights granted and the availability of the river throughout the life of the PHAM project.

In conformity with commitments made in meetings held with the management of the El Manzano Channel at the offices of Gener between January and October 2008, Gener has agreed to underwrite the construction of new infrastructure necessary in order to ensure water capture from the Colorado River to which that community possesses legally granted rights, as well as to pay all additional maintenance costs that the community may incur as a consequence of the operation of the PHAM. Furthermore, Gener will pay all additional costs payable by the community to the DGA for corresponding permit applications.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see **Table 2.3.4**

in Chapter 2 of the EIS.

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that is, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02 "Hanging" channels

Gener has repeatedly issued declarations that it is aware that not only the works that it shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact

shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of**

flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum.**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility

(Addendum, Section 5, Question 2).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station Northing	Coordinates (UTM) Easting
---------------	-----------------------------	--------------------------------------

Remarks and Responses

Alto Volcán	Stream gauge station La Engorda Stream Bridge	406,157	6,259,100
Alto Volcán	Rain gauge station El Volcán River Bridge (Volcán	460,487	6,358,143
Alto Volcán	Control Station La Engorda Intake	407,468	6,259,751
Alto Volcán	Control Station Las Placas Intake	406,780	6,260,782
Alto Volcán	Control Station Colina Intake	407,181	6,260,081

Colorado River	Intake control station Colorado River	389,063	6,292,501

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 102

Restrictions Placed on the Usage of Water Rights in the Yeso River

- * Gener holds rights over water in the Yeso River amounting to 15 m³/sec. These rights were granted without ecological flow rate requirements. The Project plans to abstract 15 m³/sec Of water 700 m downstream of the reservoir.
- * Although the original rights acquired do not contain a stipulated ecological flow rate, this measure should be imposed by the SEIA as a mitigation measures - that is, a restriction on the usage of the rights held.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively. Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 from the year 1990, in the Public Registry of Water Usage Rights, maintained by the Public Water Registry (Catastro Público De Aguas) (**see the Addendum, Section V, Question 24, Part vi**).

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4 in Chapter 2 of the EIS**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating

in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of

Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of flow rates and water levels**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. 	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

PRO.01 Regulations

A plan has been prepared addressing compliance with environmental regulation legislation applicable to the Project, as stipulated and specified in Article 12 part g) of Law 19,300, and Article 12 part d) of Ministry of the General Secretariat of the Presidency of the Republic Supreme Decree 95.01, which sets the recast text of the Regulations on the Environmental Impact Evaluation System (RSEIA), indicating the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and the sector environmental permits that the Project will require for its execution (EIS, Chapter 3, Section 3.1) **Chapter 3 of the EIS** provides detailed information on:

- The legal framework within which the Project was designed;
- The oversight bodies tasked with enforcing compliance in matters subject to regulation;

- The ways in which the Project will ensure compliance with these regulations. The Project Owner is obligated to comply strictly with legislation in force, and the bodies tasked with enforcing this compliance are the governmental and state bodies specified in the same legislation.

PRO.O 1.01 Compensation

The concept of compensation refers to the act of indemnifying damages or harm caused. Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS).

In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

Remark N° 103

Tourism

- * Given that, in view of its characteristics and natural monuments, the Cajón del Maipo valley has been declared a ZOIT Zone of National Interest, the Project Owner is requested to analyze and evaluate to what extent the impacts to be generated by the PHAM in the area subject to intervention are compatible with the district's role as a tourism destination.
 - * The Project Owner must identify the current and potential tourism demand in the region, in both qualitative and quantitative terms.
 - * Determine tourism service availability in the context of demand.
- * Describe and classify the tourism companies with special interests considered in the district, and the promotion of tourism service provision in the area.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative,

that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism Scenery**

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.01 River sports

During the operations phase, the activities of the PHAM shall not directly or indirectly interfere with tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. Furthermore, the PHAM shall have no significant effect on boating activities on the Maipo River as a result of reductions in river flow rate; an analysis is presented in Annex 17 of the Addendum modeling a number of hydrological scenarios (1), concluding that the PHAM shall not affect the current situation in rafting and kayaking activities conducted in the area between San Gabriel and San José de Maipo.

In order to establish an analysis comparing the current Maipo River boating situation with predictions for the situation with the Project operational, the variables of flow rate, river width, and water depth were modeled, as valid indices to establish conditions for boating activities on the Maipo River.

This analysis showed that the Project shall not interfere with tourism activities conducted on the Maipo River, in view of estimates that in a dry year, the magnitude of variations in flow rate and water depth will not cause interference with boating activities.

For more information, see **Annex 17 of Addendum 1**.

- (1) The hydrological analysis used to evaluate reductions in flow rate is based on a statistical record going back 50 years, thus ensuring that seasonal and annual variations are incorporated into the analyses conducted.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business

initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 104

Ecological flow rates

- * The ecological flow rate should be defined by the DGA, not by the Project Owner
- * The point where these flow rates is to be measured and monitored should be sited at the mouth of the Colorado River.
- * Flow rate monitoring should include the participation of outside agencies, that are not hired by the company.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of

habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of flow rates and water levels**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Q_e) approved by the DGA. In the case of the PHAM,

the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses. Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Eastings	Northing
	Alto Volcán	Stream gauge station	6,259,100
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 105

Decline in Flow Rates

*The impact to arise as a result of the decline in flow rates in the watercourses subject to intervention is not a cosmetic effect that is justified through the absence of tourism-related infrastructure.

*The Project Owner must provide documented background information forming the grounds for the prediction, identification, and interpretation of the impact that these actions shall cause.

* It should also describe the actions that it shall take in order to prevent or minimize all significantly negative effects.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.04 Monitoring and control of flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also

biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project. For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 106 Impact in Watercourses Subject to Intervention

The Project Owner should take into account variables arising as a result of the formation of flat, open watercourses at a level closer to the surface. Temperature increased from sunlight, loss of water through evaporation, and the process of eutrophication can arise as a result of these conditions.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally

complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of flow rates and water levels**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Q_e) approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 107 Transfer of Water Rights

The approval of transfer of title over water rights should be subject to the maintenance of ecological flow rates established by the DGA.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-

-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively.

Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 of the year 1990, with Registry Number 202 in the Public Registry of Water Usage Rights (available for examination in **Section V, Question 24, Section vi of the Addendum**).

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El

Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order

to maintain ecosystems. The operation and construction of the power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

Remark N° 108 CONAMA EIS

Given that the principal functions of CONAMA include "Administration of the EIS System", why is it permitted that a project be resubmitted when it intentionally omits, for instance, the impact to be generated in an entire settlement, as is the case in El Manzano? The same situation occurs regarding all of the watercourses subject to intervention under this project, the impact of which is described as a "cosmetic effect". In Law 19,300, Art. 2, Part c, it is stated that "**Environmental damage** [means] any significant loss, decline, detriment, or harm caused to the environment, or to one or more of its components", and the Project Owner has clearly recast environmental damage as a cosmetic effect in order to obtain its RCA. CONAMA, in its role as the administrator, should not only reject the resubmission of the PHAM under these conditions, it should also apply sanctions against this situation.

Thematic responses

OTR Other

This section relates to certain special situations that could not be categorized, or that are linked to specific requests, disqualifications, or situations that feature a clear political component, against either the environmental authority or the Project Owner.

OTR.02 CONAMA

Remark N° 109 **Citizen Participation Meetings**

At these meetings the Project Owner makes presentations, and these presentations are riddled with omissions, distortions, and bare faced lies. This fact has been observed by all of those present, including CONAMA, should be cause for drastic sanctions, and not aided by silence on the part of CONAMA.

Both the EIS system and the citizen participation meeting system should be subject to self-assessment, in terms of efficiency and transparency.

Thematic responses

OTR Other

This section relates to certain special situations that could not be categorized, or that are linked to specific requests, disqualifications, or situations that feature a clear political component, against either the environmental authority or the Project Owner.

OTR.02 CONAMA

Remark N° 110

Evaluation of the EIS System

An EIS should provide documented background information that can be used to predict, identify, and interpret its environmental impact and describe the action or actions that it shall take in order to prevent or minimize all significant adverse effects, so that, based on this background information, the project can be evaluated - in this case, by COREMA.

However, the PHAM Project Owner has not included this background information. (E.g. Impact at El Manzano); we must therefore assume that COREMA is to magically guess this impact, in order to make its observations on the project.

What happens if it is not capable of magical guessing? This clearly shows that the system as it is currently used is not efficient; that it is a system that can and should be improved, as the question of whether the correct information reaches those who are to make decisions regarding this project cannot be entrusted to the community.

- The inclusion of omissions, distortions, and falsified data in a EIS with the aim of obtaining an RCA, without accepting the cost of the impacts concerned, should be seen as a crime and sanctioned as such.

Thematic responses

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles,

70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.01 Regulations

The Project Owner shall comply with all legal environmental and sector-based regulations and requirements in force and applicable to the Project during the different phases of its development. The Project Owner has guaranteed compliance with the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and compliance with sector environmental permits.

Environmental regulations that apply to the Project have been identified based on its activities' potential environmental impacts affecting flora and fauna. The full extent of these regulations is included in **Chapters 3 and 4 of the EIS, and in Section 2, Question 1 in Addendum 1.**

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph

(EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

**PRO.02 EIS Additional and
Complementary Information**

In accordance with consultation procedures conducted by oversight services, further studies

and information have been incorporated into Addendum 1, which complements existing information provided in the EIS. Regarding ecological flow rates (**Annex 17**), cultural heritage (**Annex 14**) and the management of summer grazing areas (**Annex 6**).

Remark N° 111 1. Water Rights

The Project does not hold concessions for water rights at any abstraction point. A technical report exists, issued by the DGA, that concludes that it would not be possible to make available the water rights requested by Gener because there is no physical availability of water. How can a project of this nature be evaluated if it does not hold the required water rights? Will the Project attempt to take over water rights held by third parties?

Furthermore, a vast number of complaints have been lodged opposing these transfers of rights, in the Upper Maipo area and in the Colorado River.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively.

Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 of the year 1990, with Registry Number 202 in the Public Registry of Water Usage Rights (available for examination in **Section V, Question 24, Section vi of the Addendum**).

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in
**Chapter 2 of the
EIS.**

AGU.04 Water flow in rivers and

streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

Remark N° 113

3. Ecological Flow Rates and Baseline Studies

The Project establishes an ecological flow rate for the Colorado River at 0.6 m³/s. This flow rate is outside of the bounds stipulated by law, requiring (as a minimum) that the value must be 10% of average annual flow rate - in this case, 3.1 m³/s plus environmental demand.

Our studies indicate that downstream of the intakes, the Yeso River dries out, the La Engorda Stream dries out, the Colina Stream dries out, the Las Placas Stream dries out, the Morado Stream dries out, and the Colorado River is left with a minimal flow rate. Ecological flow rates are determined based on the Environment Base Law, Law 19,300, and respecting rights held by third parties.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications

in the natural state of the hydrological system relate to the presence of the Alfafal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of

Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of flow rates and water levels**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
	Alto Volcán		
	Rain gauge station		
	406,157		
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
Alto Volcán	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
Alto Volcán	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
Alto Volcán	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
Alto Volcán	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
Yeso River	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
Yeso River	PBN (15)		
Yeso River	Control station	399,666	6,272,077

Colorado River	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
Colorado River	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 114

4. Impact on Sediments and Aggregates

The potential aggregates production in the river basin will decline by around 3 million tons per year, which equates to more than 22% of total. This will affect the infrastructure of intakes, bridges, and water abstraction works, as well as the specific activity of aggregates extraction. If the authority has imposed a freeze on aggregates extraction permits in the first section of the Maipo River, how can it grant permission for a project that will extract 22% of all aggregates produced in the river basin?

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.05.01 Drinking water quality

The process of hydroelectric power generation does not affect the physical/chemical qualities of water. Additionally, the PHAM does not plan to implement regulation installations that retain sediment. Thirdly, downstream of the discharge point the natural river conditions are maintained with regard to flow rate and physical/chemical properties.

During the construction of installations to be located in watercourses, the free-flowing course of the river is maintained through the construction of diversions through pipes laid along the river course for such purposes, or through channels that divert all flow, allowing free water circulation with no effect whatsoever on quality (see **Section I, Question 28, in the Addendum**).

The Project owner shall not make use of the Lo Encañado Lake or water usage rights owned by Aguas Andinas S.A. for this Project, instead opting to forgo usage of these resources and to replace the role that would have been fulfilled by the Lo Encañado Lake with a forebay located on a widening of the Alfalfal II plant headworks, located in the Alto Aucayes area on the Colorado River Valley (for details, see **EIS 2.2.1**). The Lo Encañado area shall be assigned a status of controlled access area at all times: it shall not be subject to any intervention whatsoever. The Project Owner has made available a Water Quality Monitoring Program, with specifications for application during both the construction and operations phases. This program espouses a commitment to verify the effectiveness of environmental control measures designed to minimize the effects of works construction activities during the construction phase.

For further information on the Monitoring Program, see **Sections 8.2 and 8.3 in**

Chapter 8 of the EIS.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfal Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on

background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity. It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence. Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area. The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (AGU.06.01), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity. Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence. Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted. It can be concluded that the Maipo River system can be managed such that, With the Project operational, present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them. Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river. In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level. It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be identical to those currently observed. It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times of the year flow rate in the Maipo River watercourse drops significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake owned by Aguas Andinas, etc. Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual abstraction rate at these intakes varies between 78 and 164 m³/second. This situation clearly explains the high level of perturbation observed in the behavior of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years. It is for this reason that the Project Owner asserts that its activities will have no impact on the current situation in the sand extraction sites located on the Maipo River.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district. In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district. During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain

climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for

group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. The study also investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 115

5. Impact on aquatic flora and fauna

The Maipo Valley features an extremely high level of plant diversity, which has been studied by renowned botanists. Its aquatic plant and animal life also show a diversity of species described. No impact study has been conducted regarding high diversity aquatic plant and animal life, in an area that is designated by laws as a Priority Biodiversity Conservation Area.

Thematic responses

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles,

70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3, and Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neoporteria curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo Spinolosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Lilolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed

will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

F&F.02.02 Mitigation

Aquatic flora and fauna

The Project calls for a suite of multi-purpose environmental management measures that aim to minimize its effects on living organisms, including: minimization of watercourse areas to be subject to intervention by prioritizing such works for late summer and early fall seasons (period of lowest flow rates), the adoption of special precautions to prevent accidental spillages into watercourses (prohibition of the storage of lubricant drums in or near watercourses, etc), and permanent maintenance of ecological flow rates.

For more detailed information, including technical documentation that complements the information described above, see Annex 17 of the Addendum.

Terrestrial Flora and Vegetation

In order to prevent and/or minimize the Project's effects on plant life, it plans to adopt a number of integrative measures: micro-routing in advance of starting work on-site, in order to identify specimens of plants listed in any conservation category and subject to impact; compensation with the planting of 10 specimens for every one destroyed, in the case of non-woodland species listed for conservation; implementation of a woodland management plan applicable to woodland areas, which describes its measures in accordance with Article 5 of the Woodland Law; implementation of vegetation restoration plans at muck disposal sites, encampments, artificial slopes, and tunnel access terraces (EIS, Annexes 7 and 29). More in-depth information on complementary measures is provided in Annex 6 of Addendum 1.

Terrestrial fauna

Specific wildlife environmental management measures have been proposed for each particular species, taking into account prior experience in the success of these measures in similar projects. These measures will be implemented in continual coordination with the Servicio Agrícola y Ganadero. Principal measures include: capture of individuals belonging to species of conservation interest for rescue and relocation; controlled perturbation actions; and habitat replacement. Other measures are based on the use of signage, training for Contractors, and contractual requirements for on-site supervision (see details in Section 6.4.1.6 of the EIS).

See Annex 4 of the Addendum for the native wildlife rescue and relocation plan.

Remark N° 116

6. Sustainability in the Maipo River Basin

The Company does not hold the corresponding water rights, and the Baseline studies are therefore not valid. The Project does not comply with the Environmental Impact Assessment System. The company does not recognize the impacts that shall arise as a result of the extraction of water resources. The Project is not capable of generating 530 MW. Data studied indicate that the company does not possess the water resources necessary to operate the Project, and does not hold corresponding water rights.

The Gener PHAM Project is not compatible with the sustainability of the Maipo River Basin.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively.

Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 of the year 1990, with Registry Number 202 in the Public Registry of Water Usage Rights (available for examination in **Section V, Question 24, Section vi of the Addendum**).

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.03.01 Water resources

The baseline studies used in determining existing water resources in the Project area are presented in **Chapter 5.3.5 of the EIS.**

This section presents information characterizing the basins and tributaries of the Volcán,

Yeso, and Colorado Rivers, all in the context of the Maipo River Mountain Hydrological System. This characterization describes the current situation of the aspects that are of relevance in the environmental evaluation, and in particular the features related to flow dynamics and the usage of water resources.

A number of sources have been used in the preparation of this characterization: various environmental studies belonging to the Directorate-General of Water (DGA), Meteorological Department of Chile, and Aguas Andinas, as well as the Water Resource Analysis reports conducted by Gener, which are attached in Annex 13 of Addendum 1; this information was used to determine the monthly average flow rates for each of the rivers and streams involved in the Project.

For more in-depth information on water resource baseline information, see **Annexes 13 and 17 of the Addendum, and Section 5.7.1.3 of the EIS.**

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

Remark N° 117 Sediments and Aggregates Transported by the Maipo River

As a result of water abstraction in the higher reaches of the river basin, Annex 20 of the Environmental Impact Study indicates that there will be a decline in the transport of aggregates by the river, and in its capacity to transport sediment. What impact will this situation have on the river's sandbanks, and on the extractions of aggregates where legal concessions exist for this activity? This situation is a threat to legally constituted rights, and to sources of employment related to the extraction and sale of aggregates for use in construction. Many families living in San José de Maipo have traditionally made their living through this activity and, with rights to do so legally constituted, continue to do so.

This impact on the resources is **NEGATIVE AND IRREVERSIBLE** (implying their destruction) and therefore must be taken into account.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediments

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**Chapter 6.1 of the Sedimentation Study** presented in **Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river.

In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level.

It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be identical to those currently observed.

It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times

of the year flow rate in the Maipo River watercourse drops significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake

owned by
Agua
Andinas, etc.

Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual abstraction rate at these intakes varies between 78 and 164 m³/second.

This situation clearly explains the high level of perturbation observed in the behavior of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years.

It is for this reason that the Project Owner asserts that its activities will have no impact on the current situation in the sand extraction sites located on the Maipo River.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. The study also investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 118

1. Water Rights

The Project does not hold concessions for water rights at any abstraction point. A report prepared by the Directorate General of Water (DGA) indicates that this water does not physically exist, and that if any rights come to be granted, the flow rate in question will not be known; therefore, the baseline study is not valid, as it is based on suppositions regarding flow rates.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.01.02 Transfer of Rights

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project.

Table 2.3.4, which is included in **Chapter 2 of the EIS**, provides details of the instream water usage rights, both permanent and for future usage, continuous and non-continuous, that are to be used by Gener for the operation of the Alto Maipo Hydroelectric Project (PHAM). For each case information is provided on the corresponding riverbed, flow rates granted, intake and point of discharge back into the watercourse, resolutions whereby the rights were granted, and inscription in the corresponding Real Estate Registry.

In order to adjust the rights held by Gener S.A. to the needs of the Alto Maipo Hydroelectric Project, a number of documentary procedures have been submitted to the Dirección General de Aguas (DGA) for the transfer of instream water usage rights, as specified in files VT-1302-226, VT-1302-227, VT-1302-228, VT-1302-229, VT-1302-230, and VT-1302-231, relating to the Las Placas, Maipo Valley, Morado, La Engorda Stream, Colina Stream, Yeso River, and Colorado River watercourses, respectively.

Gener is the holder of rights for the instream usage of 2 m³/s of water from the Aucayes Stream, on a permanent and continuous basis; this right is inscribed in the Puente Alto CBR, sheet 343 N° 536 of the year 1990, with Registry Number 202 in the Public Registry of Water Usage Rights (available for examination in **Section V, Question 24, Section vi of the Addendum**).

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see **Table 2.3.4** in **Chapter 2 of the EIS.**

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site

information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information,

see **Annex 17** of the **Addendum**.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

Remark N° 119

2. Impact on Production Activities: Tourism

The Project is designed to minimize impact on tourism infrastructure, with point classifications and in relation with highway-related issues. This activity's real-world contribution to the District must be identified, along with the way in which it will be affected by reductions in flow rates, damage to ecosystems, access to mountain areas, impact on the landscape from power transmission lines.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally

complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's

high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **ELE Electrical Installations**

The electrical installations presented in the EIS comprise the substation, to be located in the El Sauce area, the characteristics of which are to be found in **Annex 27 of the EIS**; given that the electricity transport layout (cabling and towers) is to be presented to the Environmental Impact Assessment System once all background information is available.

ELE.03 Transmission lines

In view of the project's location, close to Santiago, it is expected that the distance covered by the definitive cabling layout will be short, involving a minimum of sectors not subject to prior intervention. With regard to the specific location of the cabling layout, plans call for the use of the existing high tension power line used by the Queltehues, Volcán, and Maitenes Plants.

Once the layout of the high tension power line has been defined, the Project Owner will submit this plan to the Environmental Impact Assessment System, in accordance with legislation in force. In line with the development of the Compliance Plan for environmental legislation applicable to the Project, the General Regulations applicable in this instance are indicated below:

Decree with Force of Law N°4, dated 05 February, 2007, setting forth the Recast, Coordinated, and Systematized Text of the General Law on Electrical Services.

The General Law on Electrical Services governs the generation, transmission, distribution, and regimen of concessions and tariffs applicable to electrical energy, and the functions of the State with regard to these areas.

Supreme Decree N° 327, Regulations Regarding the General Law on Electrical Services

The Regulations Regarding the General Law on Electrical Services establish, in their 8th Article, that hydroelectric power plants, electrical substations, and transmission lines may be installed without making a request for a concession, when the interested party wishes. These concessions may be provisional (in order to study projects) or definitive. A definitive concession is granted by a supreme decree issued by the Ministry of the Economy, by order of the President of the Republic. Permits relating to electrical installations that do not require concessions are granted by the corresponding Municipal Governments.

For further information and analysis on the aforementioned regulations, with regard to the Project, as well as in terms of general aspects, compliance, and regulatory bodies, please see **Sections 3.1.6 and 3.1.7 of Chapter 3 of the EIS**, where more detailed versions of this information can be found.

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3**, and **Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neopteris curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Liolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed

will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor.

(see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

TUR Tourism

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.01 River sports

During the operations phase, the activities of the PHAM shall not directly or indirectly interfere with tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. Furthermore, the PHAM shall have no significant effect on boating activities on the Maipo River as a result of reductions in river flow rate; an analysis is presented in Annex 17 of the Addendum modeling a number of hydrological scenarios (1), concluding that the PHAM shall not affect the current situation in rafting and kayaking activities conducted in the area between San Gabriel and San José de Maipo.

In order to establish an analysis comparing the current Maipo River boating situation with predictions for the situation with the Project operational, the variables of flow rate, river width, and water depth were modeled, as valid indices to establish conditions for boating activities on the Maipo River.

This analysis showed that the Project shall not interfere with tourism activities conducted on the Maipo River, in view of estimates that in a dry year, the magnitude of variations in flow rate and water depth will not cause interference with boating activities.

For more information, see **Annex 17 of Addendum 1**.

- (1) The hydrological analysis used to evaluate reductions in flow rate is based on a statistical record going back 50 years, thus ensuring that seasonal and annual variations are incorporated into the analyses conducted.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the

possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

TUR.03 Visual impact

The Project Owner has conducted a study to characterize the landscape of the area in which

the Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and continue throughout the working life of the Project. A qualitative methodology is used to study these effects, whereby the first phase consists of identifying sources of visual impact, and the second phase relates to identifying and classifying environmental impacts.

As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention.

As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access roads.

For further information on the methodology used for landscape impact assessment, see **Chapter 6, Section 6.1.4.10 of the EIS, and Annex 17 of Addendum 1.**

Remark N° 122 Difference of US\$100,000,000

If the Project has reduced its area of influence, why have the costs risen by US\$ 100,000,000 (one hundred million dollars) over and above the costing for the original project? This is a very large difference to be an error in calculation, and therefore **I want to know what this money will be used for, and who will receive this money?** As, during the citizen participation process, the company stated that everything about this project is transparent, please provide transparency regarding the money that the project is donating and giving away, and which funds belong to the project itself

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term

mutually beneficial relationships between the project and its surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

Remark N° 123 Saving Us from an Energy Crisis

In its arguments in favor, the company indicates that it intends for this project to save the country from an energy crisis. My question is: **does the company really believe that it will be able to save the country from an energy crisis with this project, as it indicated in its meeting with local residents? Or is it only saying this so that people see a solution to this problem, and finally choose to support the project, even though the statements made at the meetings with citizens will not be proved true? Will it or will it not save the country? Please do not reply that it is just a contribution; answer yes or no.**

Thematic responses

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

Remark N° 124 Landscape Change and Change in Water Composition

Does the company really believe that, by taking water from the Upper Maipo River, allowing only fine sediment to pass, and discarding coarser material into the natural watercourse, it will not change the scenery of the Upper Maipo River - once the river is left without the capacity to transport this sediment, rather allowing it to build up over the years? And the composition of the water?

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum.**

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

Remark N° 125 Drinking Water in San Alfonso and at Other Sites

Can the company Gener offer assurances that it will not affect the wells that supply drinking water to the town of San Alfonso when part of the river dries out, or other wells in the area, through effects on groundwater?

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in
**Chapter 2 of the
EIS.**

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.03.03 Underground water

Underground water will not be affected in any way by the operation of the Project. This is the case because the underground water flow capacity in each sector of the aquifer associated with the Maipo River is much lower than the minimum flow running through each section of the river, and therefore under all circumstances the aquifers shall remain saturated. Thus, underground water sources present in the area shall also not be affected.

The PHAM plans to construct 70 km of tunnels, of which approximately 50 km correspond to headworks or hydraulic pressure tunnels, the remainder being access tunnels for use during construction of the project and for subsequent operation of the power plants (see **EIS Chapter 5, Section 5.3.5.3**).

Most of these tunnels have been designed to operate at variable internal pressures, with a maximum achieved at certain points of a little more than 450 m. The design requirement for these tunnels is that the lower limit of principal compression in the surrounding rock medium is always less than the operating pressure, such as to maintain a sufficient safety margin to prevent alterations in natural permeability dynamics through hydrojacking. In areas where this design principle is not guaranteed, the Project plans to install impermeable tunnel linings (**EIS, Annex 45.4**).

During the excavation of these tunnels, it is possible that the work front may have to pass through permeable rock strata - leading to seepages of water into the tunnel, the magnitude of which will depend on the permeability of the rock, the depth of the tunnel, and the level of the water table. In some areas, tunnel wall treatments may have to be applied in order to prevent water transfer into or out of the headworks tunnels.

The Project does not plan to make use of any water seepages that may arise, in the generation of electricity. Additionally, the overarching design principles underpinning the Project are oriented towards limiting seepages during construction, in order to establish suitable conditions for efficient tunnel excavation activities. The same principle applies to methods to limit the infiltration of water from the tunnels into the rock mass, thus avoiding water loss during operations.

Additionally, these procedures guarantee that any groundwater that may intercept the tunnels

shall suffer no change in its natural hydrological dynamics, or impact on any

foreign components or water other than the water entering the system (**EIS, Annex 45**). Special attention will be paid to the quality and characteristics of any water that may eventually return to the natural water system through the tunnel access windows, and therefore construction contracts will specify measurements that must be made and the treatment that shall be required for subsequent disposal of such water, in order to ensure compliance with the quality requirements for water discharge into natural watercourses, under regulations currently in force.

In the event of seepages of water at high temperature and possible acidic composition, it is important to make clear that in general there shall be no major differences in the methods used to render the tunnel walls impermeable. During all site surveys conducted, research boreholes and surface geological maps produced to date applying to the areas through which the tunnels will pass, no evidence whatsoever has been found to lead to any prediction of the presence of water at high temperatures, or with mineral or acidic contamination. As additional background information, during the construction of the Alfalfal Plant - with the excavation of 35 km of tunnels - no events similar to those indicated above occurred. Notwithstanding the above, the specification establish that, in locations located close to potentially critical areas, the contractor must drill survey boreholes of between 25 m and 30 m in length ahead of the tunnel work front, in order to gain early warning of seepage problems and thus be able to apply impermeable tunnel wall treatments as required. See **EIS, Annex 45.4**.

Remark N° 126 Insurance

Will the company Gener contract the insurance policies that any project of this scale should hold, such as agricultural insurance, and policies covering all risks to local residents; or, what policies will be held?

Thematic responses

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly

frequented, minimizing their visual impact.

PRO.01 Regulations

A plan has been prepared addressing compliance with environmental regulation legislation applicable to the Project, as stipulated and specified in Article 12 part g) of Law 19,300, and Article 12 part d) of Ministry of the General Secretariat of the Presidency of the Republic Supreme Decree 95.01, which sets the recast text of the Regulations on the Environmental Impact Evaluation System (RSEIA), indicating the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and the sector environmental permits that the Project will require for its execution (EIS, Chapter 3, Section 3.1)

Chapter 3 of the EIS provides detailed information on:

- The legal framework within which the Project was designed;
- The oversight bodies tasked with enforcing compliance in matters subject to regulation;
- The ways in which the Project will ensure compliance with these regulations.

The Project Owner is obligated to comply strictly with legislation in force, and the bodies tasked with enforcing this compliance are the governmental and state bodies specified in the same legislation.

PRO.01.02 Insurance

Notwithstanding the fact that legislation in force does not impose an obligation on the Project Owner to contract insurance, it is the policy of the Risk Management Department of the Gener group to maintain civil responsibility insurance policies covering damages to third parties or injuries to its personnel and damage to its property, covering both the construction and operations phases of its Projects. Notwithstanding the above, in the event that activities related to the construction or operation of its installations for the PHAM Project cause harm to third parties, the liability and the amount awarded as compensation for damages suffered must be determined by the courts.

SUE Soil Impact

The baseline studies used in determining the soil characteristics of the Project area are presented in **Section 5.3.4 of the EIS**. Complementary information is provided in **response 32 xiii in Section 5 of Addendum 1**. In general, the District of San José de Maipo features low soil quality, as a result of its topographic and geomorphological characteristics. According to a study conducted by the Instituto de Investigaciones de Recursos Naturales (IREN) (Pérez, W.; Tamayo, A.: 1996), most soils in the District are classified as dryland non-arable soils.

In the land areas that form the Project's area of influence, and in particular in the upper reaches of the Yeso River and Volcán River sub-basins and in the middle reaches of the Colorado River, current usage patterns are strongly influenced by relief characteristics and conditions, and prevailing high mountain climate conditions, which bring about a number of limiting factors - including physical factors and accessibility factors - affecting the development of human activities.

SUE.03 Agriculture

It should be pointed out that the main irrigation channels fed from the Maipo River have their intakes located downstream of the La Sirena Channel intake, which itself is located approximately 1 km downstream of the Las Lajas Power Plant discharge spillway.

Only the Maurino and Manzano Channels have their intakes located on the Colorado River. In the case of the channels that draw water from the Colorado River, the Project Owner has agreed to construct such additional works as are required at the channel intakes, and to accept responsibility for maintaining these installations.

The Project shall have no effect on the availability of water resources used for irrigation, as the points where the PHAM will capture and discharge the water that it uses are all located upstream of the area in question.

Remark N° 127 Metropolitan Master Plan

Will the Project Owner comply with the Metropolitan Master Plan - yes or no?

Thematic responses

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly

frequented, minimizing their visual impact.

PRO.01 Regulations

A plan has been prepared addressing compliance with environmental regulation legislation applicable to the Project, as stipulated and specified in Article 12 part g) of Law 19,300, and Article 12 part d) of Ministry of the General Secretariat of the Presidency of the Republic Supreme Decree 95.01, which sets the recast text of the Regulations on the Environmental Impact Evaluation System (RSEIA), indicating the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and the sector environmental permits that the Project will require for its execution (EIS, Chapter 3, Section 3.1)

Chapter 3 of the EIS provides detailed information on:

- The legal framework within which the Project was designed;
- The oversight bodies tasked with enforcing compliance in matters subject to regulation;
- The ways in which the Project will ensure compliance with these regulations.

The Project Owner is obligated to comply strictly with legislation in force, and the bodies tasked with enforcing this compliance are the governmental and state bodies specified in the same legislation.

Remark N° 128 El Morado Natural Monument

Will the Project pass underneath the El Morado Natural Monument or any similar site - yes or no?

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.02 Tunnels

The majority of the Project is planned for installation underground. The general characteristics of the tunnels are described in Chapter 2 of the EIS, Table 2.2.5 (for detailed geological information on the path taken by the tunnels, see Annex 46 of the EIS).

For an evaluation of the impact and environmental management measures associated with underground installations, see Chapter 6 of the EIS.

Annex 45 of the EIS, Hydro-Geology of Underground Works, presents a general description of the geological conditions that are expected to be found along the lengths of the tunnels; expected permeability based on geological knowledge and hydro-geological conditions in the area, incorporating experience gained during the construction of tunnels for the Alfalfal Plant, which has been operative for more than 17 years; as well as a description that includes the design of the tunnels, providing a brief explanation of the methods to be used to reduce and control water seepage.

With regard to the impact of the path taken by the tunnel passing underneath the El Morado Natural Monument, and measures to be taken to respect the area, see Section I, Responses 4, 5, and 6, in the Addendum.

Remark N° 129 Installed Power

Please state what will be the real power generated by the project. Also, state whether charges will be levied for installed power capacity. Given that in this case there is a great difference between the power generating potential of the Project's hydrological characteristics and the power capacity being installed, what is the reason for the magnitude of this difference, if sufficient water resources are not available?

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.03.01 Water resources

The baseline studies used in determining existing water resources in the Project area are presented in **Chapter 5.3.5 of the EIS**.

This section presents information characterizing the basins and tributaries of the Volcán, Yeso, and Colorado Rivers, all in the context of the Maipo River Mountain Hydrological System. This characterization describes the current situation of the aspects that are of relevance in the environmental evaluation, and in particular the features related to flow dynamics and the usage of water resources.

A number of sources have been used in the preparation of this characterization: various environmental studies belonging to the Directorate-General of Water (DGA), Meteorological Department of Chile, and Aguas Andinas, as well as the Water Resource Analysis reports conducted by Gener, which are attached in Annex 13 of Addendum 1; this information was used to determine the monthly average flow rates for each of the rivers and streams involved in the Project.

For more in-depth information on water resource baseline information, see **Annexes 13 and 17 of the Addendum, and Section 5.7.1.3 of the EIS**.

ELE Electrical Installations

The electrical installations presented in the EIS comprise the substation, to be located in the El Sauce area, the characteristics of which are to be found in **Annex 27 of the EIS**; given that the electricity transport layout (cabling and towers) is to be presented to the Environmental Impact Assessment System once all background information is available.

ELE.03 Transmission lines

In view of the project's location, close to Santiago, it is expected that the distance covered by the definitive cabling layout will be short, involving a minimum of sectors not subject to prior intervention. With regard to the specific location of the cabling layout, plans call for the use of the existing high tension power line used by the Queltehues, Volcán, and Maitenes Plants.

Once the layout of the high tension power line has been defined, the Project Owner will submit this plan to the Environmental Impact Assessment System, in accordance with legislation in force. In line with the development of the Compliance Plan for environmental legislation applicable to the Project, the General Regulations applicable in this instance are indicated below:

Decree with Force of Law N°4, dated 05 February, 2007, setting forth the Recast, Coordinated, and Systematized Text of the General Law on Electrical Services.

The General Law on Electrical Services governs the generation, transmission, distribution, and regimen of concessions and tariffs applicable to electrical energy, and the functions of the State with regard to these areas.

Supreme Decree N° 327, Regulations Regarding the General Law on Electrical

The Regulations Regarding the General Law on Electrical Services establish, in their 8th Article, that hydroelectric power plants, electrical substations, and transmission lines may be installed without making a request for a concession, when the interested party wishes. These concessions may be provisional (in order to study projects) or definitive. A definitive concession is granted by a supreme decree issued by the Ministry of the Economy, by order of the President of the Republic. Permits relating to electrical installations that do not require concessions are granted by the corresponding Municipal Governments.

For further information and analysis on the aforementioned regulations, with regard to the Project, as well as in terms of general aspects, compliance, and regulatory bodies, please see **Sections 3.1.6 and 3.1.7 of Chapter 3 of the EIS**, where more detailed versions of this information can be found.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

Remark N° 131 Improper Legal Framework

How is the future of the PHAM predicted for the next 50 years, within the current legal framework for energy?

Thematic responses

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

Remark N° 132 Improper Legal Framework

How will the PHAM continue to maintain dialog with the community, with no legal framework?

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes

Maitenes Foundation agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

Remark N° 133 Project Incomplete

Transmission

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

Remark N° 135 **Regional and Provincial Situation**

The position of the State regarding the role of the Project as part of the general perspective.

Thematic responses

OTR Other

This section relates to certain special situations that could not be categorized, or that are linked to specific requests, disqualifications, or situations that feature a clear political component, against either the environmental authority or the Project Owner.

OTR.02 CONAMA

Remark N° 136 Technological Changes

Of the lungs of the City

- The Project accepts (assumes) that technology will not change.

Thematic responses

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

SLD Health Impact

The Project owner shall take responsibility for ensuring compliance with health and safety regulations, in order to prevent any possible risk to health and physical integrity for the inhabitants of San José Maipo as well as the persons working on the Project.

SLD.02 Atmospheric

Although the Project involves surface construction activities, which will lead to the emission of particulate matter, plans call for the implementation of a suite of mitigation measures that will result in a considerable reduction in emission, not only of the PHAM itself but also as against the baseline of current particulate emissions through the Project's area of influence. In addition to the above, these considerations should be evaluated bearing in mind the fact that most of the Project's works will be underground, not producing any emissions of particulate matter.

Conversely, given that most of the Project's works are to be located in high mountain areas, it can be stated that the prevailing ventilation conditions in this environment will facilitate the dispersion of dust, with a natural reduction in emissions during the winter season as a result of the additional moisture contributed by rain and snow precipitation.

For more information on emissions compensation measures, see **Annex 5 of the EIS**.

Remark N° 137

Guarantees

- Environmentalists state that this project will cause an environmental catastrophe
- The company AES Gener states that the impacts will be minimal

The question is as follows: does a baseline study exist in the EIS that presents a snapshot of the ecological and environmental situation (biomass, wildlife, relative humidity, etc.)?

If the "environmentalists" are right, what measures will be taken to "guarantee" continuity as against the baseline, with regard to our ecology and environment?

1. Quantity and quality of plant life
2. Quantity and quality of wildlife
3. Relative humidity characteristics

We are not "fortune tellers", projecting the project's "real" environmental impacts is not an exact science. Let's guarantee the District's environmental future.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.04.04 Monitoring and control of flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
Alto Volcán	Stream gauge station	406,157	6,259,100
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán		
Alto Volcán	Control Station	407,468	6,259,751
	La Engorda Intake		

Alto Volcán	Control Station Las Placas Intake	406,780	6,260,782
Alto Volcán	Control Station Colina Intake	407,181	6,260,081

Remarks and Responses

Remark N° 137 Page 2

Alto Volcán	Control Station El Morado Intake	405,768	6,261,231
Yeso River	Rain gauge station PBN (15)	391,504	6,262,449
Yeso River	Control Station El Yeso Intake	399,666	6,272,077
Colorado River	Stream gauge station El Sauce	380,449	6,287,261
Colorado River	Intake control station Colorado River	389,063	6,292,501

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

F&F Biodiversity Impact Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3, and Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempe Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neoporteria curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Lilolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals

will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).
No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

Remark N° 138

5% of the PHAM Project's earnings must be given to the District.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes

Maitenes Foundation agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

Remark N° 139 Reduction in Water Flow Rates

As I own land alongside the Colorado River, I need water to maintain environmental moisture.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in
**Chapter 2 of the
EIS.**

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that it, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

Remark N° 140 Tourism

Tourism demand, in qualitative and quantitative terms

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism

is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism**

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.01 River sports

During the operations phase, the activities of the PHAM shall not directly or indirectly interfere with tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. Furthermore, the PHAM shall have no significant effect on boating activities on the Maipo River as a result of reductions in river flow rate; an analysis is presented in Annex 17 of the Addendum modeling a number of hydrological scenarios (1), concluding that the PHAM shall not affect the current situation in

rafting and kayaking activities conducted in the area between San Gabriel and San José de Maipo.

In order to establish an analysis comparing the current Maipo River boating situation with predictions for the situation with the Project operational, the variables of flow rate, river width, and water depth were modeled, as valid indices to establish conditions for boating activities on the Maipo River.

This analysis showed that the Project shall not interfere with tourism activities conducted on the Maipo River, in view of estimates that in a dry year, the magnitude of variations in flow rate and water depth will not cause interference with boating activities.

For more information, see **Annex 17 of Addendum 1**.

- (1) The hydrological analysis used to evaluate reductions in flow rate is based on a statistical record going back 50 years, thus ensuring that seasonal and annual variations are incorporated into the analyses conducted.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 141 Water Rights

Respect third party water rights, and ensure that the holders of such rights are respected in the long term.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services. For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4 in Chapter 2 of the EIS.**

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been

conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape. To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a

description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of flow rates and water levels**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Eastings	Northing
	Alto Volcán		
	406,157		
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 142**Irrigation** **User**
Communities

El Manzano Channel and

Maurino Channel

Thematic responses

Specific Response

The Project Owner reiterates its commitment to ensuring that necessary infrastructure exists in the river to permit water to enter the channels at all times, in accordance with the rights granted and the availability of the river throughout the life of the PHAM project.

In conformity with commitments made in meetings held with the management of the El Manzano Channel at the offices of Gener between January and October 2008, Gener has agreed to underwrite the construction of new infrastructure necessary in order to ensure water capture from the Colorado River to which that community possesses legally granted rights, as well as to pay all additional maintenance costs that the community may incur as a consequence of the operation of the PHAM. Furthermore, Gener will pay all additional costs payable by the community to the DGA for corresponding permit applications.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water**rights**

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in
Chapter 2 of the
EIS.

AGU.02.01**Irrigation**

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that it, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources.

During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02 **"Hanging"**
channels

Gener has repeatedly issued declarations that it is aware that not only the works that it shall construct, but also the usage that it shall apply to in-stream water rights that it holds,

shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

Remark N° 143 Hands Off the Colorado River

Robber barons, you don't mess with water, the natural world will make you pay for your impudence

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.01 Regulations

The Project Owner shall comply with all requirements relating to regulations that apply to water usage for the purposes of the Project; these regulations are issued by the main state services that specialize in this field. Dirección General de Aguas (Directorate General of Water, DGA), Dirección de Obras Hidráulicas (Directorate of Hydraulic Works, DOH), Servicio Agrícola y Ganadero (Agriculture and Livestock Service, SAG), and Health Services.

For details on these regulations, see **Chapter 3, Section 3.2.3 of the EIS.**

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see **Table 2.3.4** in **Chapter 2 of the EIS.**

Remark N° 144 Water

The drying out of rivers and streams will certainly cause an impact on the environment and on families.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures

designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc. Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

Remark N° 145 Glacier and Natural Monuments

The damage caused in these areas will have disastrous consequences for tourism and on local residents.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly

agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism**

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 146 Job Creation

Supposed job creation effects are not a reality that will have any effect on the local population and community in the areas affected.

Thematic responses

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

Remark N° 147 Education

The Foundations as a consolation prize to the community to generate a favorable impression of the company.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of

the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

CAL.02 Education

A goal of the Maitenes Foundation relates to education for children and young people against the backdrop of the natural environment (for more information on the goals and achievements of the Foundation, see Annex 26 of the EIS).

Gener firmly believes that contributions to the technical and vocational education and training of young people must keep sight of real employment possibilities. Therefore, as a first initiative it has earmarked resources for an education improvement project in the district, which will contribute to establishing education management for the restructuring of the school curriculum and professional technical capacity building, taking into account the features needed to boost local employability. Based on information and recommendations from this study, Gener, acting through the Maitenes Foundation, will undertake a Capacity Building for Employability Program fundamentally oriented towards those whose family, social, or economic situation has barred them from completing their education and training, or acquiring the skills needed in order to find work.

Remark N° 148 Environmental Impact

The fact that a tunnel passes beneath a glacier leads to irreparable damage to the area's ecosystem. It is also harmful to tourism in the area.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

**CAL.04 Fostering tourism
in the area**

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **PRO The Project**

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.02 Tunnels

The majority of the Project is planned for installation underground. The general characteristics of the tunnels are described in Chapter 2 of the EIS, Table 2.2.5 (for detailed geological information on the path taken by the tunnels, see Annex 46 of the EIS).

For an evaluation of the impact and environmental management measures associated with underground installations, see Chapter 6 of the EIS.

Annex 45 of the EIS, Hydro-Geology of Underground Works, presents a general description of the geological conditions that are expected to be found along the lengths of the tunnels; expected permeability based on geological knowledge and hydro-geological conditions in the area, incorporating experience gained during the construction of tunnels for the Alfalfal Plant, which has been operative for more than 17 years; as well as a description that includes the design of the tunnels, providing a brief explanation of the methods to be used to reduce and control water seepage.

With regard to the impact of the path taken by the tunnel passing underneath the El Morado Natural Monument, and measures to be taken to respect the area, see Section I, Responses 4, 5, and 6, in the Addendum.

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits

to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 149 Water

The Project for the New Hydroelectric Plants will cause a noteworthy decline in the quantity of water available for use in irrigation.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in
**Chapter 2 of the
EIS.**

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that it, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El

Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and**

Section IV, Question 5.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

Remark N° 150 Employment

The Project offers no concrete guarantees that new jobs will be created for the people who live in the area.

Thematic responses

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district. In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district. During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

Remark N° 151 Ecological flow rates

The ecological flow rates should be defined by the DGA, not by the Project Owner.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river

flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero

(0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

Remark N° 153 Decline in Flow Rates

The impact to arise as a result of the decline in flow rates in the watercourses subject to intervention is not a cosmetic effect that is justified through the absence of tourism-related infrastructure.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at

least in part. **AGU.04.04 Monitoring and control of flow rates and water levels**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Q_e) approved by the DGA. In the case of the PHAM, the analysis of Q_e has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently

subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
	Alto Volcán		
	Stream gauge station		6,259,100
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 156
Impact in Watercourses Subject to Intervention

Increase in temperature from sunlight and other factors

Thematic responses

Specific response

The watercourses subject to intervention are not susceptible to significant impact regarding sunlight or increases in temperatures.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.04 Monitoring and control of flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum.**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
Alto Volcán	Stream gauge station	406,157	6,259,100
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 157 Tourism

Given that the Cajón del Maipo valley has been declared a zone of national tourism interest, the Project Owner is requested to analyze and evaluate to what extent the impacts to be generated by the PHAM are compatible with this role.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism**

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 158 Water

To dry out rivers is to leave the community without its main source of life.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that

will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a

description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

Remark N° 159 Education

The proposals do not always provide responses to the people's real education needs, by means of the foundations.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of

the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

CAL.02 Education

A goal of the Maitenes Foundation relates to education for children and young people against the backdrop of the natural environment (for more information on the goals and achievements of the Foundation, see Annex 26 of the EIS).

Gener firmly believes that contributions to the technical and vocational education and training of young people must keep sight of real employment possibilities. Therefore, as a first initiative it has earmarked resources for an education improvement project in the district, which will contribute to establishing education management for the restructuring of the school curriculum and professional technical capacity building, taking into account the features needed to boost local employability. Based on information and recommendations from this study, Gener, acting through the Maitenes Foundation, will undertake a Capacity Building for Employability Program fundamentally oriented towards those whose family, social, or economic situation has barred them from completing their education and training, or acquiring the skills needed in order to find work.

Remark N° 160
Environment of Natural Monuments

Environmental impact, affecting tourism, on natural reserves.

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism

is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **F&F Biodiversity Impact**

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3**, and **Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neoporteria curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Liolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopus cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

TUR Tourism

Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-

term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives

coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

**Remark N° 161
Employment**

Employment proposals and offers often lack necessary physical conditions, or are not in the interests of the community.

Thematic responses

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district. In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district. During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

SOC.01.02 Working conditions

To date no schedule exists specifying labor requirements for the full duration of the construction phase. Detailed information specifying jobs created under average and peak labor requirements, broken down by labor requirement dynamics for each encampment, will only be available once the Project Owner has tendered the works contracts.

During the operations phase, it is expected that personnel requirements will amount to approximately 80 positions available, required for power plant operations and maintenance activities. Unlike work positions created during the construction phase, the jobs created in the operations phase will be permanent (EIS, Chapter 6, Section 6.4.2.4).

The Project Owner will provide for coordination between the construction works contractors, the Labor Brokerage Office, and the Municipality of San José de Maipo, regarding local labor required and jobs sought. The PHAM has accepted a commitment to incentivize works contractors to prioritize local contracting of labor required.

No prior training is planned in advance of the Construction Phase. However, such training will form part of the programs implemented in the more advanced phases of the project.

Remark N° 162

Role of CONAMA and/or COREMA

Caring for the environment is the priority role of CONAMA, and this body therefore cannot approve the Project if it is unsafe, and given that the environment law does not specify reasonable limits on the usage of water (as shown by the ridiculous ecological flow rate proposed by AES Gener)(Why does the company establish the ecological limit)(and not you).

Thus, if CONAMA does not want to condemn the valley and its residents to misery, it must oppose the Project or impose LIMITS and CONDITIONS.

1. that the company must cede 5% of its profits to the Cajón del Maipo Valley, for social uses.
2. that it must occupy no more than 60% of river and stream flow rates in order not to cause environmental impacts.
3. that it must not prevent persons from entering high mountain areas (c.f. the case of Alfalfal I).

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at

least in part.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and

educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.01 Contributions to the community

In line with Gener's policy on local integration and cooperation with the development of the communities in which it participates, during the development of the Alto Maipo project the company's Maitenes agrees to make a concrete contribution to local education for employability, tourism promotion, sports and leisure areas, and social projects of interest to the community. In light of observations made during the citizen participation process, Gener considers such activities to be key to the growth of the district and its residents in the medium and long term. This initiative will take shape based on the recommendations of a council of community members, local authorities, and company representatives, which will be free to decide on how such resources are used.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating procedures and mechanisms for the usage of these funds and the duration of the program concerned.

This commitment will apply only if the Alto Maipo Project is executed.

OTR Other

Remarks and Responses

Remark N° 162 Page 3

This section relates to certain special situations that could not be categorized, or that are linked to specific requests, disqualifications, or situations that feature a clear political component, against either the environmental authority or the Project Owner.

OTR.02 **CONAMA**

Remark N° 164
Irrigation User Organizations, El Manzano Channel and Maurino Channel

In view of the drop in water flow in the Colorado River, irrigation user organizations will find it impossible to abstract the quantities of water to which they have rights.

1. The Project Owner should include the construction of such installations as shall be necessary to avoid this impact, and the commitment that has been expressed to defray all costs arising through the construction and maintenance of these installations.
2. The Project should include guarantees and compensation payable in the event that these organizations are rendered unable to abstract the water to which they hold rights.
3. The Project Owner should attach written consent by the “El Manzano Channel” and “Maurino Channel”

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project’s base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project’s EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project’s area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see **Table 2.3.4** in **Chapter 2 of the EIS**.

AGU.02.01
Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project’s area of influence - that it, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02 **“Hanging”**
channels

Gener has repeatedly issued declarations that it is aware that not only the works that it shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

PRO.01.01 Compensation

The concept of compensation refers to the act of indemnifying damages or harm caused. Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS).

In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

Remark N° 169

Precautionary Measures to Maintain Ecological Flow Rates

- * Precautionary measures should be indicated that will be taken to ensure the maintenance of ecological flow rates along all applicable watercourses and throughout the year.
- * The Project Owner should take into account variables arising as a result of the formation of flat, open watercourses at a level closer to the surface. Temperature increased from sunlight, loss of water through evaporation, and the process of eutrophication can arise as a result of these conditions.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4 in Chapter 2 of the EIS**.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known

as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow

velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included. In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.04.04 Monitoring and control of flow rates and water levels**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
	Alto Volcán		
	Rain gauge station		
	406,157		
	Stream gauge station		
	6,259,100		
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum**.

Remark N° 171 Morales Stream - Maipo Valley Property

With regard to the Environmental Impact Study for the project "PROYECTO HIDROELÉCTRICO ALTO MAIPO file N° 105", presented by AES Gener S.A. to the environmental impact assessment system (SEIA), in conformity with the General Base Law on the Environment, Law 19,300 dated 1994, in representation of the owners of the property at Quebrada Morales, over the surface and underground properties of which a significant part of the project will pass; we wish to express:

The PHAM will install the new "Alfalfal II" power plant in the upper reaches of the Maipo River and shall make use of water from the upper reaches of the Volcán River and the Yeso River.

Most of the Project's installations shall be located underground, including the turbine rooms and headworks, as indicated in Project documentation, but the fact that the works are underground does not mean that they may not create prior impacts and destruction of surface land to which the Project has access.

The Project's access roads and water intakes constitute its main surface works and installations. Plans also call for the creation of a **Muck Disposal Heap** that will receive all material produced through the excavation of this tunnel.

The construction of the Alfalfal II Plant water discharge spillway implies the installation of the **Muck Disposal Heap** containing materials removed in the creation of this installation, and the installation of temporary or permanent encampments, as well as movement of persons or goods for a sufficient time to bring about the destruction of the area of great archeological and paleontological interest known as "EL VALLE DE LAS ARENAS", which forms part of the Quebrada Morales land holding owned by Messrs. Von Plate Harries.

This area known as the "**Valle Las Arenas**" is included in the National System of Protected Private Wilderness Areas (SNAPP), which is legally protected under Law 19,300.

Law 19,300 defines environmental damage as "any significant loss, decline, detriment, or harm caused to the environment, or to one or more of its components"

The term "environment" is understood to refer not only to natural elements but also to artificial and socio-cultural elements; Article 10 part p) requires the application of the environmental impact evaluation system to a number of classes of project, including the implementation of any works in any area placed under official protection, such as archeological and paleontological remains that, as a result of their characteristics, are protected under the National Monuments Law.

Under Chilean legislation, in the absence of a soil law or land law, and in view of the precarious treatment of cultural and scenic heritage provided under the General Urban Development and Construction Law, the environmental impact evaluation system takes on a role as a vital legal instrument that, operating under the precautionary principle, permits the reconciliation of due protection for goods belonging to cultural heritage and the execution of projects or activities that may form sources of environmental impact, with the aim of ensuring that irreplaceable sites such as those with anthropological, archeological, historic, and other classes of value causes them to be classed as natural and cultural heritage are granted special consideration in the evaluation that must be conducted for the project.

The El Alfalfal II Project, with its works located within the "**Valle Las Arenas**" area, and particularly the siting of the Muck Disposal Heap and the installation of an encampment with consequent movements of persons and vehicles, nonetheless plans for no measure to protect or prevent damage to the natural and archeological riches located at that site.

On the contrary, the project documentation refrains from making any mention of the "Valle Las Arenas" area. It does not indicate that these works will form the start of a process of irreparable damage, which will cause the archeological, paleontological, and natural sites such as wetlands, all located on the mountain pass to the "**El Morado Glacier**", shall no longer possess their original scientific and natural potential. Similarly, in the project documentation no protection or damage prevention measures have been presented for this important area, which rather contains incomplete background information that fails to specify such basic figures as the quantity of muck, in tons or cubic meters, derived from the construction of the tunnel and to be disposed of at the Muck Disposal Heap to be installed in that valley.

"**Valle de Las Arenas**" is recognized by the global scientific community, and certain members of this community have expressed their concern over the international installation, some of whom have expressed their concern over the installation of this project in that valley, with regard to which we refer to the report by geologist Christian Salazar Soto and Professor Doctor Wolfgang Stinnesbeck, a geologist and paleontologist, both members of the University of Heidelberg, Germany, in the *Informe de la Sociedad de Paleontología de Chile* as well as the municipal government of San José de Maipo - all of which publication warn of severe environmental damage to the area, and to which we claim a link as owners of the aforementioned land holding.

It has been the intention of the landowners to incorporate the "**Valles Las Arenas**" into protected national heritage in view of its enormous tourism potential, and its unique and irreplaceable archeological and paleontological remains. For this reason work has been conducted on this "**Private Protected Wilderness Area**" under the legal protection granted to private interests promoting the development of such areas for the development of sustainable projects, which, maintaining protection of their unique properties, can be the subject of top level tourism projects that bring great economic benefits to the area.

Any person interested in the "**VALLE LAS ARENAS**" can view its website: www.vallelasarenas.cl which provides all necessary information on its content and significance.

Finally, it is requested that all necessary reports relating to the temporary and permanent occupation of the Valle Las Arenas be requested, relating to the construction of the project, and providing detailed and precise specification of the area and volume of the muck disposal heap that shall remain permanently in this region; and furthermore, that an opinion be issued with regard to the mechanisms to be applied to the protection of existing wetlands and fossils in that area.

In view of the above, attention is hereby called to the destruction represented by works to be

conducted in the "Valle Las Arenas" in its role as a "**Private Protected Wilderness Area**", as well as the irreparable environmental risks to be visited upon the area, which will result in any

other environmental or tourism project in the area becoming unfeasible, thus impeding the successful completion of sustainable projects that respect the environment.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

AGU.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum 1**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

ARQ.03 Scientific research

The scientific and cultural importance of the paleontological resources present has been recognized by the PHAM Project Owner, leading to a practice of taking particular care in selecting locations of works sites and installations in the Alto Volcán area, so as to protect and prevent the deterioration of all recorded or known resources. At the same time, the Project Owner has taken on a commitment to enhance knowledge of the area before starting planned works, undertaking survey studies of the Alto Volcán area, in parallel with suitable protection for sites recorded in that zone, as well as any new finds that may be detected during the course of construction under the PHAM. These activities will contribute not only to the maintenance of the aforementioned resources, but shall also add to the recognition of the sites where they are found.

Thus, in the framework of procedures for the approval of the EIS, all available information on the most significant earth science materials and components has been compiled, as applicable to the PHAM area and surroundings, forming part of the country's non-renewable scientific/cultural heritage. Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of

materials or components present.

For more information, see **Annex 14 of Addendum 1**.

MAR Muck

The PHAM plans to construct approximately 70 km of tunnels. The excavation of these tunnels will generate inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of inert material produced in road building and the construction of buried conduits.

This muck material will be deposited in the 14 muck disposal heaps that the Project plans to create. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria. For more information, please see **Annex 6 of the EIS** and **Annex 3 of the Addendum**.

MAR.01 Regulations

The Project Owner has made available a Management Plan for "Project Muck Disposal Heaps", which contains information on the technical, environmental, and safety specifications of the heaps, as well as recommendations contained in the Ministry of Public Works' 2004 Environmental Management Plan Manual for Works Subject to Concessions. In particular, the Plan establishes the environmental considerations adopted for the operation of the muck disposal heaps, to be implemented during the construction of tunnels and roads under the PHAM.

In order to comply with the environmental management measures contained in the EIS, an Environmental Monitoring Program will be conducted, with the aim of verifying the effectiveness of these measures and compliance with them. For details on the principal actions included in the Monitoring Program, and for the various stages of functionality of the muck disposal sites, see **Annex 6 of the EIS** and **Annex 3 of Addendum 1**.

For more information on the specific regulations applicable to the Project, and compliance therewith, see **Chapter 3 of the EIS**.

MAR.02 Location

The PHAM calls for the creation of 14 muck disposal heaps, for the disposal of waste material from tunnel boring and smaller quantities of inert waste from the construction of roads and buried conduits. Maps of the muck disposal heaps, and a copy of the muck disposal heap management plan, are included in Annex 6 of the Project EIS.

For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria.

From a technical and safety perspective, the muck disposal heap sites have been located as close as possible to exit points from tunnels and to surface work sites, in areas not at risk to landslides or landslip events.

The following aspects have been taken into account as environmental criteria in site selection:

Sites have been selected that are distant from any settlements or any housing used on a permanent or temporary basis.

Priority has been given to selecting sites with low visual impact - that is, in areas that are distant from potential observation points on public highways or high ground.

In the Project area's higher elevation regions, the disposal heaps have been sited up against natural topological features, such that the emplacement of the heaps' layers forms a continuation of the general landform structures of the area.

In general these are areas that are of low value as a habitat for plant life (soils with usage capacity ratings V, VI, and VII), and efforts have been made to avoid modifications to the original land form structures present or to surface watercourses.

Surface surveys have been conducted in all of these regions, as details in **Section 5.8, in Chapter 5 of the EIS**, to rule out the presence of sites of archeological and/or paleontological value at the muck disposal heap sites.

For more information, see **Annex 6 of the EIS** and **Annex 3 of Addendum 1**.

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum 1**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

ARQ.03 Scientific research

the scientific and cultural importance of the paleontological resources present has been recognized by the PHAM Project Owner,

leading to a practice of taking particular care in selecting locations of works sites and installations in the Alto Volcán area, so as to protect and prevent the deterioration of all recorded or known resources. At the same time, the Project Owner has taken on a commitment to enhance knowledge of the area before starting planned works, undertaking survey studies of the Alto Volcán area, in parallel with suitable protection for sites recorded in that zone, as well as any new finds that may be detected during the course of construction under the PHAM. These activities will contribute not only to the maintenance of the aforementioned resources, but shall also add to the recognition of the sites where they are found.

Thus, in the framework of procedures for the approval of the EIS, all available information on the most significant earth science materials and components has been compiled, as applicable to the PHAM area and surroundings, forming part of the country's non-renewable scientific/cultural heritage. Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects of this project, particularly where justified by the heritage significance of materials or components present.

For more information, see **Annex 14** of **Addendum 1**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

Remark N° 173

Baseline

V.6 Cultural Heritage

According to the text of the EIS

“Three areas within the Project’s area of direct influence are identified as featuring resources of cultural interest: Las Morrenas and Camino del Inka in the Lo Encañado Lake area, and the site known as Aucayes 1 in the Colorado River - Aucayes Stream area. The “Las Morrenas” site is currently in a good state of conservation, the “Camino del Inka” site exhibits significant impact arising as a result of the construction of a water conduit that is currently not in use, and meanwhile the Aucayes 1 exhibits no apparent human or natural impact. In the Alto Volcán area, sites have been detected that may contain very ancient fossils or paleontological material.. Much of this material has been removed by tourists and residents of local settlements (according to background information available to the SPACH) Works under the PHAM shall not lead to any direct intervention”.

- **The Chilean Paleontological Society states that no reference has been made to the issue of tourists and local residents in relation to paleontological heritage, in communications with the company AES Gener. Additionally, we wish to make it clear that works under the PHAM do lead to intervention affecting fossil evidence.**

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project’s area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project’s area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

ARQ.02 Values preservation

General paleontological protection measures:

i) **Restricted area applicable to contractor company employees**

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a “restricted zone” with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) **Delimitation of buffer zones**

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) **Contingency measures**

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project’s paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) **Compensation measures**

- a) **production of cultural information material**
- b) **creation of a viewpoint**
- c) **fossil trail**

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District’s high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plant (**EIS, Chapter 8**); together, these measures

are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism Scenery**

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 174**5. Identification, Prediction, and Evaluation of Environmental Impacts and Risk Situations****Environmental Evaluation**

According to the table in the EIS

I. Table 7: Hierarchy of Environmental Impacts

Construction phase

Elements or variables:

Cultural Heritage

Impact:

Three areas with resources of archaeological interest and one area of paleontological interest have been identified within the Project's area of indirect influence. Continual on-site expert advisory services will be contracted to prevent or minimize impact

Classification

Negative; Low significance

- **SPACH remark. According to information available, the sites of paleontological interest will be located within the project's area of direct influence. To which site is reference made with regard to the area of indirect influence?**

Thematic responses**ARQ Archeological and Paleontological Sites: Heritage**

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

ARQ.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
 - Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
 - Archeological recovery plan for any finds discovered during expert supervision.
 - Workforce training on the possible presence of archeological sites.
 - Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum**.
- 1.

Remark N° 175

Chapter 2. Project Description

2.3 Description of Project Phases

2.3.2 Construction Phase

2.3.2.4 Creation of Encampments and Works Installations

According to the text of the EIS

A. Siting criteria

"Finally, and in accordance with the baseline study, the sites defined for the installation of site facilities and encampments have been surveyed by specialists, and the results of these surveys have, on a preliminary basis, ruled out the presence of findings and sites with archaeological or historic value, or belonging to national cultural heritage, or plant species listed in any conservation category "

- **SPACH remark. According to paleontological information available, sites with heritage value exist in the areas defined for the installation of site facilities and encampments.**

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

ARQ.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum**.

1.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned

to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.03 Encampments and Works Installations

For details on the creation of encampments and works installations, please see Chapter 2, Section 2.3.2.4 in the EIS.

For information on PHAM encampment and work site approach routes, see EIS, Chapter 2, Table 2.1.2,

For information on regulations, see Chapter 3 of the EIS and Annex 33, General Operating Regulations for Encampments and Work Sites.

For information on the management of waste produced at work sites and encampments, see Annex 18 of the EIS, "Site Installation Waste Management Plan".

For information on the discharge of treated wastewater, see Response 26 in the Addendum. For information on human consumption of water at encampments and works installations, see Chapter 2, Section 2.3.2.4, parts b and i.

For an assessments of the impact of the creation of encampments and works installations, monitoring methods, and conditions, see Chapter 6 of the EIS.

Remark N° 176

2.3.2.6 Muck Disposal Heap Sites

According to the text of the EIS

A. Siting

"The following aspects have been taken into account as environmental criteria in site selection:

- Surface surveys have been conducted in all of these regions to rule out the presence of sites of archeological and/or paleontological value"

- **SPACH remark. According to information available, sites with paleontological value exist in the areas defined for the Alto Volcán muck disposal heap.**

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

MAR Muck

The PHAM plans to construct approximately 70 km of tunnels. The excavation of these tunnels will generate inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of inert material produced in road building and the construction of buried conduits.

This muck material will be deposited in the 14 muck disposal heaps that the Project plans to create. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria. For more information, please see **Annex 6 of the EIS** and **Annex 3 of the Addendum**.

MAR.02 Location

The PHAM calls for the creation of 14 muck disposal heaps, for the disposal of waste material from tunnel boring and smaller quantities of inert waste from the construction of roads and buried conduits. Maps of the muck disposal heaps, and a copy of the muck disposal heap management plan, are included in Annex 6 of the Project EIS. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria.

From a technical and safety perspective, the muck disposal heap sites have been located as close as possible to exit points from tunnels and to surface work sites, in areas not at risk to landslides or landslip events.

The following aspects have been taken into account as environmental criteria in site selection: Sites have been selected that are distant from any settlements or any housing used on a permanent or temporary basis.

Priority has been given to selecting sites with low visual impact - that is, in areas that are distant from potential observation points on public highways or high ground.

In the Project area's higher elevation regions, the disposal heaps have been sited up against natural topological features, such that the emplacement of the heaps' layers forms a continuation of the general landform structures of the area.

In general these are areas that are of low value as a habitat for plant life (soils with usage capacity ratings V, VI, and VII), and efforts have been made to avoid modifications to the original land form structures present or to surface watercourses.

Surface surveys have been conducted in all of these regions, as details in **Section 5.8, in Chapter 5 of the EIS**, to rule out the presence of sites of archeological and/or paleontological value at the muck disposal heap sites.

For more information, see **Annex 6 of the EIS** and **Annex 3 of Addendum 1**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly

frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water

abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El

Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

Remark N° 177

Chapter 4. Relevance of the Environmental Impact Evaluation System (SEIA) and

Need to Conduct an Environmental Impact Study.

4.3 Analysis of Articles 5 to 11 of the SEIA Regulations.

4.3.6 Article 11

- SPACH remark.

Cases a) and b) show proximity, and furthermore, sites corresponding to paleontological heritage exist that shall be subject to direct intervention. In the Alto Volcán area, the Lo Valdés Formation will be affected by the construction of the El Volcán Tunnel, which passes through and destroys the formation. The same area features ichnites (fossilized vertebrate tracks) in blocks, belonging to the Rio Damas Formation, particularly in the Valle de las Arenas.

The SPACH has reported the presence of these sites, and has been vocal in communication with the Project Owner AES Gener in its assertions that the PHAM will cause direct intervention on paleontological heritage, which will be affected by surface and underground works, or works requiring excavation.

The SPACH expresses its concern, given that it is not in agreement with the conclusion reached by AES Gener in this regard, as paleontological heritage will be subject to significant intervention under the PHAM.

Thematic responses

ARQ Archeological and Paleontological Heritage Sites:

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

ARQ.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum 1**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint

c) fossil trail

For more information and details on the preservation of heritage value and

paleontological resources, please see **Annex 14 of Addendum 1**.

OTR Other

This section relates to certain special situations that could not be categorized, or that are linked to specific requests, disqualifications, or situations that feature a clear political component, against either the environmental authority or the Project Owner.

PRO.02 EIS Additional and Complementary Information

In accordance with consultation procedures conducted by oversight services, further studies and information have been incorporated into Addendum 1, which complements existing information provided in the EIS. Regarding ecological flow rates (**Annex 17**), cultural heritage (**Annex 14**) and the management of summer grazing areas (**Annex 6**).

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.02 Tunnels

The majority of the Project is planned for installation underground. The general characteristics of the tunnels are described in Chapter 2 of the EIS, Table 2.2.5 (for detailed geological information on the path taken by the tunnels, see Annex 46 of the EIS).

For an evaluation of the impact and environmental management measures associated with underground installations, see Chapter 6 of the EIS.

Annex 45 of the EIS, Hydro-Geology of Underground Works, presents a general description of the geological conditions that are expected to be found along the lengths of the tunnels; expected permeability based on geological knowledge and hydro-geological conditions in the area, incorporating experience gained during the construction of tunnels for the Alfalfal Plant, which has been operative for more than 17 years; as well as a description that includes the design of the tunnels, providing a brief explanation of the methods to be used to reduce and control water seepage.

With regard to the impact of the path taken by the tunnel passing underneath the El Morado Natural Monument, and measures to be taken to respect the area, see Section I, Responses 4, 5, and 6, in the Addendum.

Remark N° 178
Chapter V. Baseline
5.6 Existing Buildings
5.6.2 Economic and Production Activities
5.6.2.4 Tourism Sector
D. El Volcán, Baños Morales, and Lo Valdés
area. I. Current Tourism Activities
Rock hunting and archeological research

- SPACH remark. This point mentions the sale of fossils as an activity related to tourism, although this activity is illegal.

Thematic responses

**ARQ Archeological and
Paleontological Sites: Heritage**

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual

conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **TUR Tourism Scenery**

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-

related traffic flow during

weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 179

5.8 Cultural Heritage, Paleontological Resources; Background Information on the Study Area

The Chilean Paleontological Society addressed letters to the CMN, Cordillera Provincial Government, CONAMA, Municipal Government of San José de Maipo, and AES Gener, expressing its concern regarding damage that will be caused to paleontological heritage in the Alto Volcán area, stating

that damage will be caused to geological units such as the Lo Valdés, Colimapu, and Rio Damas formations, which have shown evidence of fossils. Attached to these letters, it included the **“Preliminary Report on Material of Paleontological Interest in the Alto Río Volcán Area”**, prepared by Dr. Karen Moreno, regarding the ichnites (fossilized vertebrate tracks) in blocks, belonging to the Rio Damas Formation, located in the Valle de las Arenas.

In view of existing knowledge regarding the area to be subject to intervention under the PHAM, the SPACH indicates that direct intervention affecting paleontological heritage will indeed occur.

5.8.5 Conclusions

SPACH expresses the conclusion that it is not in agreement with the presence of paleontological resources, as direct intervention affecting these resources clearly does exist. It is necessary to conduct a paleontological survey, research activities, and subsequent monitoring of waste rock if the PHAM goes ahead, which activities should be conducted by qualified professionals.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project’s area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project’s area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a “restricted zone” with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project’s paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

ARQ.03 Scientific research

The scientific and cultural importance of the paleontological resources present has been recognized by the PHAM Project Owner, leading to a practice of taking particular care in selecting locations of works sites and installations in the Alto Volcán area, so as to protect and prevent the deterioration of all recorded or known resources. At the same time, the Project Owner has taken on a commitment to enhance knowledge of the area before starting planned works, undertaking survey studies of the Alto Volcán area, in parallel with suitable protection for sites recorded in that zone, as well as any new finds that may be detected during the course of construction under the PHAM. These activities will contribute not only to the maintenance of the aforementioned resources, but shall also add to the recognition of the sites where they are found.

Thus, in the framework of procedures for the approval of the EIS, all available information on the most significant earth science materials and components has been compiled, as applicable to the PHAM area and surroundings, forming part of the country’s non-renewable scientific/cultural heritage. Additionally, the documentation addresses preventive and contingency measures to be implemented in order to minimize the possible effects

of this project, particularly where justified by the heritage significance of materials or components present.
For more information, see **Annex 14** of **Addendum 1**.

Remark N° 180

Chapter 6. Impact Evaluation and Environmental Management Measures

6.4 Impact Evaluation and Environmental Management Measures

6.4.1 Construction Phase

6.4.1.9 Interference with Tourism Activities

I) Identification and Sources of Impact

- Alto Volcán Sector

- SPACH remark. Contrary to statements made by AES Gener in its EIS, at this point it is indeed our belief that sites of paleontological cultural interest will be affected.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

ARQ.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be

implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.01 Intakes

The Alto Maipo Hydroelectric Project (PHAM) plans to capture water resources at eight different points. The Project holds in-stream water rights at each of these points, and the concessions granting rights at most of these points include ecological flow rate stipulations issued by the Directorate General of Water (DGA).

The water intake points are as follows:

For the Alfalfal II Plant: the El Morado Stream, the La Engorda Stream, the Colina Stream, the Las Placas Creek, and the Yeso River. For the Las Lajas Plant: the Alfalfal Plant discharge, and the Colorado River at the Maitenes Intake. For a detailed description of planned installations, see Chapter 2, Section 2.2.2 of the EIS, and attached Annexes 1 and 8.

See Annex 12 of the EIS for a map of intakes in the PHAM area of influence. See Table 2.2.2, in Chapter 2 of the EIS, for the characteristics and descriptions of the intake installation.

For information on the Project's impact on water quality in the area's watercourses arising as a result of the construction of intakes, see Section I, Question 3 in the Addendum.

For the intake maintenance plan, the Chapter 2, Section 2.2.2 of the EIS, and additional information provided in Section I, Question 11 of the Addendum.

For clarifications regarding the El Yeso Reservoir, see Section I, question 27 in the Addendum.

For details on the construction methods and the mitigation and compensation measures planned by the Project to address the environmental impact of the intakes, see Annex 6 of the Addendum.

PRO.03.02 Tunnels

The majority of the Project is planned for installation underground. The general characteristics of the tunnels are described in Chapter 2 of the EIS, Table 2.2.5 (for detailed geological information on the path taken by the tunnels, see Annex 46 of the EIS).

For an evaluation of the impact and environmental management measures associated with underground installations, see Chapter 6 of the EIS.

Annex 45 of the EIS, Hydro-Geology of Underground Works, presents a general description of the geological conditions that are expected to be found along the lengths of the tunnels; expected permeability based on geological knowledge and hydro-geological conditions in the area, incorporating experience gained during the construction of tunnels for the Alfalfal Plant, which has been operative for more than 17 years; as well as a description that includes the design of the tunnels, providing a brief explanation of the methods to be used to reduce and control water seepage.

With regard to the impact of the path taken by the tunnel passing underneath the El Morado Natural Monument, and measures to be taken to respect the area, see Section I, Responses 4, 5, and 6, in the Addendum.

Remark N° 181
Chapter 7. Environmental
Management Plan
7.2 Environmental Risk Control and Prevention Plan.
7.2.1 Identification of Environmental Risks
7.2.1.2 Description of Risks Generated by
Human Intervention
iv) Risk of Accidental Interference with Items of Cultural
Value

According to the text of the EIS

"Additionally, the Project Owner recognizes the existence of paleontological sites in the Alto Volcán area, and that although these sites are located close to the area where certain surface construction activities are to be conducted, they will not be affected. This issue was rectified at a meeting between the Project Owner and the Chilean Paleontological Society".

The Chilean Paleontological Society refutes the statements made by the Project Owner in the text quoted above, and indicates that at a meeting held with AES Gener on January 3, 2008, it made clear to that company's representatives that, according to background information available, the Project would affect sites of paleontological interest, whether works were conducted on the surface or underground (El Volcán Tunnel). Specifically, surface works were planned for implementation in sites of paleontological interest. Additionally, the damage to be caused to paleontological sites by the El Volcán Tunnel would be a pressing concern, referring to the Lo Valdés Formation, through which the tunnel would pass.

Thematic responses

ARQ Archeological and Paleontological Heritage Sites:

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

AGU.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) **production of cultural information material**
- b) **creation of a viewpoint**
- c) **fossil trail**

For more information and details on the preservation of heritage value and

paleontological resources, please see **Annex 14 of Addendum 1**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.01 Intakes

The Alto Maipo Hydroelectric Project (PHAM) plans to capture water resources at eight different points. The Project holds in-stream water rights at each of these points, and the concessions granting rights at most of these points include ecological flow rate stipulations issued by the Directorate General of Water (DGA).

The water intake points are as follows:

For the Alfalfal II Plant: the El Morado Stream, the La Engorda Stream, the Colina Stream, the Las Placas Creek, and the Yeso River. For the Las Lajas Plant: the Alfalfal Plant discharge, and the Colorado River at the Maitenes Intake. For a detailed description of planned installations, see Chapter 2, Section 2.2.2 of the EIS, and attached Annexes 1 and 8.

See Annex 12 of the EIS for a map of intakes in the PHAM area of influence. See Table 2.2.2, in Chapter 2 of the EIS, for the characteristics and descriptions of the intake installation.

For information on the Project's impact on water quality in the area's watercourses arising as a result of the construction of intakes, see Section I, Question 3 in the Addendum.

For the intake maintenance plan, the Chapter 2, Section 2.2.2 of the EIS, and additional information provided in Section I, Question 11 of the Addendum.

For clarifications regarding the El Yeso Reservoir, see Section I, question 27 in the Addendum.

For details on the construction methods and the mitigation and compensation measures planned by the Project to address the environmental impact of the intakes, see Annex 6 of the Addendum.

PRO.03.02 Tunnels

The majority of the Project is planned for installation underground. The general characteristics of the tunnels are described in Chapter 2 of the EIS, Table 2.2.5 (for detailed geological information on the path taken by the tunnels, see Annex 46 of the EIS).

For an evaluation of the impact and environmental management measures associated with underground installations, see Chapter 6 of the EIS.

Annex 45 of the EIS, Hydro-Geology of Underground Works, presents a general description of the geological conditions that are expected to be found along the lengths of the tunnels; expected permeability based on geological knowledge and hydro-geological conditions in the area, incorporating experience gained during the construction of tunnels for the Alfalfal Plant, which has been operative for more than 17 years; as well as a description that includes the design of the tunnels, providing a brief explanation of the methods to be used to reduce and control water seepage.

With regard to the impact of the path taken by the tunnel passing underneath the El Morado Natural Monument, and measures to be taken to respect the area, see Section I, Responses 4, 5, and 6, in the Addendum.

PRO.03.03 Encampments and Works Installations

For details on the creation of encampments and works installations, please see Chapter 2, Section 2.3.2.4 in the EIS.

For information on PHAM encampment and work site approach routes, see EIS, Chapter 2, Table 2.1.2,

For information on regulations, see Chapter 3 of the EIS and Annex 33, General Operating Regulations for Encampments and Work Sites.

For information on the management of waste produced at work sites and encampments, see Annex 18 of the EIS, "Site Installation Waste Management Plan".

For information on the discharge of treated wastewater, see Response 26 in the Addendum. For information on human consumption of water at encampments and works installations, see Chapter 2, Section 2.3.2.4, parts b and i.

For an assessments of the impact of the creation of encampments and works installations, monitoring methods, and conditions, see Chapter 6 of the EIS.

Remark N° 182
7.2.6 Specific Risk Control Measures in Areas with Paleontological Resources (Valle del Arenas)

- SPACH remark. Paleontological resources may be affected by the implementation of surface and underground works.

Thematic responses

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

AGU.01 Regulations

The Project shall not affect the sites identified in the Baseline studies (**see Chapter 5 of the EIS**). Nonetheless, as a protection measures GENER shall contractually require that the works contractor implement the following measures:

- Construction of a fence running around the site in question, with at least 5 m between the perimeter of the site and the fence.
- Expert supervision by an on-site archeologist present at the Project construction site at all times. Additional periodic oversight by a paleontologist during the construction of the first part of the Volcán Tunnel.
- Archeological recovery plan for any finds discovered during expert supervision.
- Workforce training on the possible presence of archeological sites.
- Details of these risk prevention measures applicable to archeological and paleontological heritage are provided in **Chapter 7 of the EIS**, and **Annex 14 of the Addendum 1**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material
- b) creation of a viewpoint
- c) fossil trail

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect

caused by the annoyances that are typical of construction works. Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.03 Works

The PHAM Project consists of the construction and subsequent operation of two run-of-the-river hydroelectric plants in series, with a combined installed power of 531 MW. The power plants shall make use of water abstracted from the upper reaches of the La Engorda, Colina, Las Placas, and El Morado Streams and the El Yeso River downstream of the El Yeso Reservoir, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region.

The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the currently operational Alfalfal I Power Plant, and shall make use of water abstracted from Morado, Las Placas, Colina, and La Engorda Streams, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River.

The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

Most of the installations constructed for the PHAM shall be underground, including both powerhouses, siphons, and headworks - the latter consisting of tunnels. Surface construction works shall consist of the intakes, covered conduits, and new bridges over the Colorado and Yeso Rivers. Plans also call for the creation of service roads, muck disposal heaps, and temporary encampments. All temporary and permanent facilities and installations are included in the environmental evaluation.

PRO.03.01 Intakes

The Alto Maipo Hydroelectric Project (PHAM) plans to capture water resources at eight different points. The Project holds in-stream water rights at each of these points, and the concessions granting rights at most of these points include ecological flow rate stipulations issued by the Directorate General of Water (DGA).

The water intake points are as follows:

For the Alfalfal II Plant: the El Morado Stream, the La Engorda Stream, the Colina Stream, the Las Placas Creek, and the Yeso River. For the Las Lajas Plant: the Alfalfal Plant discharge, and the Colorado River at the Maitenes Intake. For a detailed description of planned installations, see Chapter 2, Section 2.2.2 of the EIS, and attached Annexes 1 and 8.

See Annex 12 of the EIS for a map of intakes in the PHAM area of influence. See Table 2.2.2, in Chapter 2 of the EIS, for the characteristics and descriptions of the intake installation.

For information on the Project's impact on water quality in the area's watercourses arising as a result of the construction of intakes, see Section I, Question 3 in the Addendum.

For the intake maintenance plan, the Chapter 2, Section 2.2.2 of the EIS, and additional information provided in Section I, Question 11 of the Addendum.

For clarifications regarding the El Yeso Reservoir, see Section I, question 27 in the Addendum.

For details on the construction methods and the mitigation and compensation measures planned by the Project to address the environmental impact of the intakes, see Annex 6 of the Addendum.

PRO.03.02 Tunnels

The majority of the Project is planned for installation underground. The general characteristics of the tunnels are described in Chapter 2 of the EIS, Table 2.2.5 (for detailed geological information on the path taken by the tunnels, see Annex 46 of the EIS).

For an evaluation of the impact and environmental management measures associated with underground installations, see Chapter 6 of the EIS.

Annex 45 of the EIS, Hydro-Geology of Underground Works, presents a general description of the geological conditions that are expected to be found along the lengths of the tunnels; expected permeability based on geological knowledge and hydro-geological conditions in the area, incorporating experience gained during the construction of tunnels for the Alfalfal Plant, which has been operative for more than 17 years; as well as a description that includes the design of the tunnels, providing a brief explanation of the methods to be used to reduce and control water seepage.

With regard to the impact of the path taken by the tunnel passing underneath the El Morado Natural Monument, and measures to be taken to respect the area, see Section I, Responses 4, 5, and 6, in the Addendum.

PRO.03.03 Encampments and Works Installations

For details on the creation of encampments and works installations, please see Chapter 2, Section 2.3.2.4 in the EIS.

For information on PHAM encampment and work site approach routes, see EIS, Chapter 2, Table 2.1.2,

For information on regulations, see Chapter 3 of the EIS and Annex 33, General Operating Regulations for Encampments and Work Sites.

For information on the management of waste produced at work sites and encampments, see Annex 18 of the EIS, "Site Installation Waste Management Plan".

For information on the discharge of treated wastewater, see Response 26 in the Addendum. For information on human consumption of water at encampments and works installations, see Chapter 2, Section 2.3.2.4, parts b and i.

For an assessments of the impact of the creation of encampments and works installations, monitoring methods, and conditions, see Chapter 6 of the EIS.

Remark N° 183 Global Issue

I believe that if this Project is not rejected then it will affect us, due to its impact on the landscape, biodiversity, the river basin equilibrium, the filling of aquifers, air quality, and quality of life.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03.01 Water resources

The baseline studies used in determining existing water resources in the Project area are presented in **Chapter 5.3.5 of the EIS**.

This section presents information characterizing the basins and tributaries of the Volcán, Yeso, and Colorado Rivers, all in the context of the Maipo River Mountain Hydrological System. This characterization describes the current situation of the aspects that are of relevance in the environmental evaluation, and in particular the features related to flow dynamics and the usage of water resources.

A number of sources have been used in the preparation of this characterization: various environmental studies belonging to the Directorate-General of Water (DGA), Meteorological Department of Chile, and Aguas Andinas, as well as the Water Resource Analysis reports conducted by Gener, which are attached in Annex

13 of Addendum 1; this information was used to determine the monthly average flow rates for each of the rivers and streams involved in the Project.

For more in-depth information on water resource baseline information, see **Annexes 13 and 17 of the Addendum, and Section 5.7.1.3 of the EIS**.

AGU.03.03 Underground water

Underground water will not be affected in any way by the operation of the Project. This is the case because the underground water flow capacity in each sector of the aquifer associated with the Maipo River is much lower than the minimum flow running through each section of the river, and therefore under all circumstances the aquifers shall remain saturated. Thus, underground water sources present in the area shall also not be affected. The PHAM plans to construct 70 km of tunnels, of which approximately 50 km correspond to headworks or hydraulic pressure tunnels, the remainder being access tunnels for use during construction of the project and for subsequent operation of the power plants (see **EIS Chapter 5, Section 5.3.5.3**).

Most of these tunnels have been designed to operate at variable internal pressures, with a maximum achieved at certain points of a little more than 450 m. The design requirement for these tunnels is that the lower limit of principal compression in the surrounding rock medium is always less than the operating pressure, such as to maintain a sufficient safety margin to prevent alterations in natural permeability dynamics through hidrojacking. In areas where this design principle is not guaranteed, the Project plans to install impermeable tunnel linings (**EIS, Annex 45.4**).

During the excavation of these tunnels, it is possible that the work front may have to pass through permeable rock strata - leading to seepages of water into the tunnel, the magnitude of which will depend on the permeability of the rock, the depth of the tunnel, and the level of the water table. In some areas, tunnel wall treatments may have to be applied in order to prevent water transfer into or out of the headworks tunnels.

The Project does not plan to make use of any water seepages that may arise, in the generation of electricity. Additionally, the overarching design principles underpinning the Project are oriented towards limiting seepages during construction, in order to establish suitable conditions for efficient

tunnel excavation activities. The same principle applies to methods to limit the infiltration of water from the tunnels into the rock mass, thus avoiding water loss during operations.

Additionally, these procedures guarantee that any groundwater that may intercept the tunnels shall suffer no change in its natural hydrological dynamics, or impact on any foreign components or water other than the water entering the system (**EIS, Annex 45**). Special attention will be paid to the quality and characteristics of any water that may eventually return to the natural water system through the tunnel access windows, and therefore construction contracts will specify measurements that must be made and the treatment that shall be required for subsequent disposal of such water, in order to ensure compliance with the quality requirements for water discharge into natural watercourses, under regulations currently in force.

In the event of seepages of water at high temperature and possible acidic composition, it is important to make clear that in general there shall be no major differences in the methods used to render the tunnel walls impermeable. During all site surveys conducted, research boreholes and surface geological maps produced to date applying to the areas through which the tunnels will pass, no evidence whatsoever has been found to lead to any prediction of the presence of water at high temperatures, or with mineral or acidic contamination. As additional background information, during the construction of the Alfalfa Plant - with the excavation of 35 km of tunnels - no events similar to those indicated above occurred. Notwithstanding the above, the specification establish that, in locations located close to potentially critical areas, the contractor must drill survey

boreholes of between 25 m and 30 m in length ahead of the tunnel work front, in order to gain early warning of seepage problems and thus be able to apply impermeable tunnel wall treatments as required. See **EIS, Annex**

45.4.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

SLD.02 Atmospheric

Although the Project involves surface construction activities, which will lead to the emission of particulate matter, plans call for the implementation of a suite of mitigation measures that will result in a considerable reduction in emission, not only of the PHAM itself but also as against the baseline of current particulate emissions through the Project's area of influence. In addition to the above, these considerations should be evaluated bearing in mind the fact that most of the Project's works will be underground, not producing any emissions of particulate matter. Conversely, given that most of the Project's works are to be located in high mountain areas, it can be stated that the prevailing ventilation conditions in this environment will facilitate the dispersion of dust, with a natural reduction in emissions during the winter season as a result of the additional moisture contributed by rain and snow precipitation.

For more information on emissions compensation measures, see **Annex**

5 of the EIS.

SUE Soil Impact

The baseline studies used in determining the soil characteristics of the Project area are presented in **Section 5.3.4 of the EIS**. Complementary information is provided in **response 32 xiii in Section 5 of Addendum 1**. In general, the District of San José de Maipo features low soil quality, as a result of its topographic and geomorphological characteristics. According to a study conducted by the Instituto de Investigaciones de Recursos Naturales (IREN) (Pérez, W.; Tamayo, A.: 1996), most soils in the District are classified as dryland non-arable soils.

In the land areas that form the Project's area of influence, and in particular in the upper reaches of the Yeso River and Volcán River sub-basins and in the middle reaches of the Colorado River, current usage patterns are strongly influenced by relief characteristics and conditions, and prevailing high mountain climate conditions, which bring about a number of limiting factors - including physical factors and accessibility factors - affecting the development of human activities.

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

Remark N° 184 Inconsistencies

The ecological flow rates calculated by the company are not sufficient to preserve aquatic and riverbank life. They do not comply with the quantitative requirements that define the concept of an ecological flow rate. They feature inconsistencies, with the extraction of quantities of water larger than those possible during certain periods. The PHAM states that only 12% of river water flow will be abstracted; this figure was checked and found not to be the case for the Maipo River (50%).

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

F&F Biodiversity Impact

Flora and
Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of

environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.01 Regulations

The Project Owner shall comply with all legal environmental and sector-based regulations and requirements in force and applicable to the Project during the different phases of its development. The Project Owner has guaranteed compliance with the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and compliance with sector environmental permits.

Environmental regulations that apply to the Project have been identified based on its activities' potential environmental impacts affecting flora and fauna. The full extent of these regulations is included in **Chapters 3 and 4 of the EIS, and in Section 2, Question 1 in Addendum 1**.

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3, and Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neopteris curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Lilolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend

to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

PRO.02 EIS Additional and Complementary Information

In accordance with consultation procedures conducted by oversight services, further studies and information have been incorporated into Addendum 1, which complements existing information provided in the EIS. Regarding ecological flow rates (**Annex 17**), cultural heritage (**Annex 14**) and the management of summer grazing areas (**Annex 6**).

Remark N° 185 River Basin Equilibrium

The equilibrium state of an ecosystem depends on the interaction of its components, and therefore a decline in moisture levels is not compatible with the preservation of the area's plant life, wildlife (habitat for a number of bird species, insects, and the Elegant Fat-tailed Mouse Opossum (*Thylamys elegans*)), or to prevent ice melt. Is the preservation of the equilibrium state guaranteed? What consideration is given to the Ministry of Mining Supreme Decree 78/06 (area of scientific mining interest)? What consideration is given to the Santiago Metropolitan Master Plan (Upper Maipo River Basin: key area of ecological preservation for the protection of high altitude wetland and stream micro-habitats)? What consideration is given to the Santiago Metropolitan Region Biodiversity Conservation Strategy (COREMA Metropolitana)?

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic

autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the

basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.01 Regulations

The Project Owner shall comply with all legal environmental and sector-based regulations and requirements in force and applicable to the Project during the different phases of its development. The Project Owner has guaranteed compliance with the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and compliance with sector environmental permits.

Environmental regulations that apply to the Project have been identified based on its activities' potential environmental impacts affecting flora and fauna. The full extent of these regulations is included in **Chapters 3 and 4 of the EIS, and in Section 2, Question 1 in Addendum 1**.

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3, and Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neoporteria curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Liolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project

Owner, see Annex 4 of the Addendum.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.01 Regulations

A plan has been prepared addressing compliance with environmental regulation legislation applicable to the Project, as stipulated and specified in Article 12 part g) of Law 19,300, and Article 12 part d) of Ministry of the General Secretariat of the Presidency of the Republic Supreme Decree 95.01, which sets the recast text of the Regulations on the Environmental Impact Evaluation System (RSEIA), indicating the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and the sector environmental permits that the Project will require for its execution (EIS, Chapter 3, Section 3.1)

Chapter 3 of the EIS provides detailed information on:

- The legal framework within which the Project was designed;
- The oversight bodies tasked with enforcing compliance in matters subject to regulation;
- The ways in which the Project will ensure compliance with these regulations.

The Project Owner is obligated to comply strictly with legislation in force, and the bodies tasked with enforcing this compliance are the governmental and state bodies specified in the same legislation.

SUE Soil Impact

The baseline studies used in determining the soil characteristics of the Project area are presented in **Section 5.3.4 of the EIS**. Complementary information is provided in **response 32 xiii in Section 5 of Addendum 1**. In general, the District of San José de Maipo features low soil quality, as a result of its topographic and geomorphological characteristics. According to a study conducted by the Instituto de Investigaciones de Recursos Naturales (IREN) (Pérez, W.; Tamayo, A.: 1996), most soils in the District are classified as dryland non-arable soils.

In the land areas that form the Project's area of influence, and in particular in the upper reaches of the Yeso River and Volcán River sub-basins and in the middle reaches of the Colorado River, current usage patterns are strongly influenced by relief characteristics and conditions, and prevailing high mountain climate conditions, which bring about a number of limiting factors - including physical factors and accessibility factors - affecting the development of human activities.

Remark N° 186 Landscape

Preserving the visual quality of the landscape is one of our priorities, as this feature is not only of significant value to residents, those who work in the area or who spend their weekends relaxing there; it is also one of the country's most heavily visited tourism areas (SERNATUR). In this remark, we include the preservation of visual contact with all features that make up the landscape (water, plants, wildlife, valleys, glaciers) at a level effectively identical to the present situation. What will happen regarding this issue? Is it guaranteed? How will muck disposal avoid affecting this issue?

Thematic responses

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term

mutually beneficial relationships between the project and its surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

**CAL.04 Fostering tourism
in the area**

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **MAR Muck**

The PHAM plans to construct approximately 70 km of tunnels. The excavation of these tunnels will generate inert material consisting of wet rock and crushed rock, known as muck, as well as smaller quantities of inert material produced in road building and the construction of buried conduits.

This muck material will be deposited in the 14 muck disposal heaps that the Project plans to create. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria. For more information, please see **Annex 6 of the EIS** and **Annex 3 of the Addendum**.

MAR.01 Regulations

The Project Owner has made available a Management Plan for "Project Muck Disposal Heaps", which contains information on the technical, environmental, and safety specifications of the heaps, as well as recommendations

contained in the Ministry of Public Works' 2004 Environmental Management Plan Manual for Works Subject to Concessions. In particular, the Plan establishes the environmental considerations adopted for the operation of the muck disposal heaps, to be implemented during the construction of tunnels and roads under the PHAM.

In order to comply with the environmental management measures contained in the EIS, an Environmental Monitoring Program will be conducted, with the aim of verifying the effectiveness of these measures and compliance with them. For details on the principal actions included in the Monitoring Program, and for the various stages of functionality of the muck disposal sites, see **Annex 6 of the EIS** and **Annex 3 of Addendum 1**.

For more information on the specific regulations applicable to the Project, and compliance therewith, see **Chapter 3 of the EIS**.

MAR.02 Location

The PHAM calls for the creation of 14 muck disposal heaps, for the disposal of waste material from tunnel boring and smaller quantities of inert waste from the construction of roads and buried conduits. Maps of the muck disposal heaps, and a copy of the muck disposal heap management plan, are included in Annex 6 of the Project EIS. For the purposes of muck disposal heap site selection, design, and management procedures, attention has been paid to technical, environmental, and safety criteria.

From a technical and safety perspective, the muck disposal heap sites have been located as close as possible to exit points from tunnels and to surface work sites, in areas not at risk to landslides or landslip events.

The following aspects have been taken into account as environmental criteria in site selection: Sites have been selected that are distant from any settlements or any housing used on a permanent or temporary basis.

Priority has been given to selecting sites with low visual impact - that is, in areas that are distant from potential observation points on public highways or high ground.

In the Project area's higher elevation regions, the disposal heaps have been sited up against natural topological features, such that the emplacement of the heaps' layers forms a continuation of the general landform structures of the area.

In general these are areas that are of low value as a habitat for plant life (soils with usage capacity ratings V, VI, and VII), and efforts have been made to avoid modifications to the original land form structures present or to surface watercourses.

Surface surveys have been conducted in all of these regions, as details in **Section 5.8, in Chapter 5 of the EIS**, to rule out the presence of sites of archeological and/or paleontological value at the muck disposal heap sites.

For more information, see **Annex 6 of the EIS** and **Annex 3 of Addendum 1**.

**TUR Tourism
Scenery**

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works, in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán.

For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02 Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is

expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.
Given that most works are to be located underground and in high mountain areas,

a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

TUR.03 Visual impact

The Project is to be located, taking into account esthetic and perceptual considerations and emphasizing the characterization and appraisal of the issues of visibility, quality, and visual fragility of the landscape.

In terms of Landscape Alteration or Landscape Impact associated with this infrastructure project, potential effects are classified as either limited duration - generally applying during the construction phase - or permanent, for effects that shall persist during the operations phase and continue throughout the working life of the Project. A qualitative methodology

is used to study these effects, whereby the first phase consists of identifying sources of visual impact, and the second phase relates to identifying and classifying environmental impacts.

As a general rule, it is assumed that impact on the landscape during the construction phase shall be temporary, mainly due to the transitory nature of the sources of impact, the low level of prior human activity in certain areas, and the relatively low level of physical and visual accessibility of a significant proportion of the area subject to intervention.

As most of the Project construction works will be situated underground, during the operations phase the main visual signatures of its existence will be the intakes and access roads. For further information on the methodology used for landscape impact assessment, see **Chapter 6, Section 6.1.4.10 of the EIS, and Annex 17 of**

Addendum 1.

Remark N° 187 Quality of Life

What will happen with truck traffic? We want an environment free of traffic congestions, air pollution, and visual and noise pollution. How will this issue be guaranteed?

Thematic responses

SLD Health Impact

The Project owner shall take responsibility for ensuring compliance with health and safety regulations, in order to prevent any possible risk to health and physical integrity for the inhabitants of San José Maipo as well as the persons working on the Project.

SLD.01 Regulations

The Project Owner is subject to specific environmental regulations that apply to the Project, determined based on environmental impacts associated with noise and air pollution during works construction and other activities. For further details, see **Chapters 3.2.2 and 3.2.1 in the EIS**. The Project Owner shall take responsibility for compliance with the monitoring plan.

SLD.02 Atmospheric

Although the Project involves surface construction activities, which will lead to the emission of particulate matter, plans call for the implementation of a suite of mitigation measures that will result in a considerable reduction in emission, not only of the PHAM itself but also as against the baseline of current particulate emissions through the Project's area of influence. In addition to the above, these considerations should be evaluated bearing in mind the fact that most of the Project's works will be underground, not producing any emissions of particulate matter. Conversely, given that most of the Project's works are to be located in high mountain areas, it can be stated that the prevailing ventilation conditions in this environment will facilitate the dispersion of dust, with a natural reduction in emissions during the winter season as a result of the additional moisture contributed by rain and snow precipitation.

For more information on emissions compensation measures, see **Annex 5 of the EIS**.

SLD.03 Acoustic

In the field of Environmental Impact, specifically acoustic impact, the Project Owner has conducted a wide-ranging study to estimate acoustic emissions generated during the construction of the PHAM. For more information on the acoustic impact of the PHAM, and methodologies, modeling techniques, and actions to be taken to minimize such impact, please see **Annex 30 of the EIS** and **Section II, Question 8 in the Addendum**.

Plans for blasting activities, specifically including the frequency, quantity, timing, and work periods of blasting, will be determined on site in accordance with the characteristics of each works activity and work site. Regarding works activity scheduling, priority will be placed on completion of surface works during the daytime (8:00-21:00 hrs.); for blasting activities, plans call for an information program at the time of the activity, defining and clarifying the periods when noise-producing activities will take place, in order to integrate the community into efforts towards the completion of the Project.

Another point worthy of emphasis is that the work sites (tunnel excavation, access windows, and entrances/exits) will not be sited close to settlements, thus preventing most of the potential acoustic impact that could be caused by the PHAM.

Wildlife rescue will be conducted through animal rescue activities based on the trapping of reptiles and amphibians before explosives are used, before service tracks are built, and before the modification of river flow.

Finally, and in order to comply with the requirements set forth above, the Project Owner shall be subject to:

1. Supreme Decree 146 (Establishing Standards on the Emission of Nuisance Noise Generated by Fixed Sources) establishing maximum permissible sound pressure levels, corrected according to technical criteria to evaluate and classify nuisance noises generated by fixed sources affecting the community, such as industrial, commercial, leisure, and artistic activities.
2. Exempt Decree 130 (Establishing restrictions on the movement of cargo trucks). The movement of trucks larger than 4 tons will be suspended from 14:00 hours on Saturdays through to midnight on each Sunday night on Route G-25 and Route G-421.

For more information on the acoustic impact of the PHAM, and regulations (Chapter 6 of the EIS), mitigation measures, methodologies, modeling techniques, and actions to be taken to minimize such impact, please see Annex 30 of the EIS, as mentioned above.

Finally, in order to verify the effectiveness of the mitigation measures taken, noise monitoring will be conducted at 8 sensitive points, following the procedure established in MINSEGPRES Supreme Decree 146/97, in order to verify compliance with the maximum permitted limits for sound pressure level (see details in **Chapter 8 of the EIS, Section 8.2.2**).

VIA Roads

The traffic analysis presented in **Annex 14 of the EIS** confirms that no significant impacts are expected to affect existing traffic and highway conditions used for access to areas of interest for tourism, archeology, and natural beauty. For more information, see **Annexes 9 and 15 of Addendum 1**. The PHAM plans call for the construction of a total of approximately 31 km of service roads, as well as the maintenance and conservation of the service roads installed by the Project Owner, and existing public and private roads, throughout the works construction phase.

VIA.03 Congestion

When PHAM Project construction activities begin, there will be an increase in road traffic movements in the immediate surroundings of the work area. This vehicle movement will be related mainly to the transport of supplies and machinery to the works installations, transport of excavation spoil to muck deposition sites, and, to a lesser extent, the transport of personnel to the work sites. For more information on traffic flow increases resulting from the Project, see **Chapter 2, section 2.4.1, part E, Annex 14 of the EIS, and Annexes 9 and 14 of Addendum 1**.

The PHAM highway impact analysis takes into account all works and activities under the Project, including the transport of supplies, machinery, and personnel. According to modeling studies, it is predicted that there will be no significant impact on highway usage (levels of saturation of new and existing roads and intersections). For more information on the Project's road operations, measurements used and models derived, see **Annexes 9 and 15 of the Addendum**. Additionally, increases in noise emissions are analyzed in **Section 6.4.1.2 of the EIS**.

Notwithstanding the above, it is assumed that, given that certain construction activities shall be conducted at the same times that other road users wish to make use of certain sections of specific roads, a certain level of annoyance may be caused, and for this reason the PHAM has adopted a number of control and mitigation measures, indicated in **Chapters 6 and 2 of the EIS** and in **Annex 14 of the EIS, as well as Annexes 9 and 17 of Addendum 1.**

It is considered likely that, in view of the predominance of the tourist industry in the local economy of the district of the Maipo Valley, a certain level of annoyance may be caused at certain points and at specific moments, mainly due to conflicts between PHAM road usage and the movements of visitors. As indicated in the EIS Baseline Study, this is an area where tourists come to enjoy walks and peace and quiet, on weekends and holidays. In particular, there are 2 specific tourism attractions located in the same areas as site installations: the El Yeso and the Alto Volcán area, where special measures shall be taken, as specified in **Chapter 6 of the Project EIS.** Additionally, **Annex 32 of the EIS** specifies emergency procedures to be adopted in the event of transport accidents caused by project vehicles.

Remark N° 188 Corporate Responsibility

What consideration will be given to the law that whoever pollutes pays for it? We want the Cajón del Maipo area to be able to conserve its present level of quality (Law 19,300). Who will take responsibility for the full magnitude of each impact? Will this be the company? Has this been demonstrated? How will effective enforcement be ensured? We are aware that this not one of the strengths of our country.

Grounding for Technical Information

Hydrological study conducted by hydraulic engineer Jack Stern. Official information provided by the DGA (database covering a period going back 70 years). Reports prepared by the Universidad de Chile, Universidad Católica, and Universidad Andrés Bello

Thematic responses

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly

frequented, minimizing their visual impact.

PRO.01 Regulations

A plan has been prepared addressing compliance with environmental regulation legislation applicable to the Project, as stipulated and specified in Article 12 part g) of Law 19,300, and Article 12 part d) of Ministry of the General Secretariat of the Presidency of the Republic Supreme Decree 95.01, which sets the recast text of the Regulations on the Environmental Impact Evaluation System (RSEIA), indicating the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and the sector environmental permits that the Project will require for its execution (EIS, Chapter 3, Section 3.1)

Chapter 3 of the EIS provides detailed information on:

- The legal framework within which the Project was designed;
- The oversight bodies tasked with enforcing compliance in matters subject to regulation;
- The ways in which the Project will ensure compliance with these regulations.

The Project Owner is obligated to comply strictly with legislation in force, and the bodies tasked with enforcing this compliance are the governmental and state bodies specified in the same legislation.

PRO.01.01 Compensation

The concept of compensation refers to the act of indemnifying damages or harm caused. Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS).

In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

Remark N° 196 Drinking Water Supply System in the Settlement of El Manzano

This settlement is not included in the Aguas Andinas S.A. concession area, nor is it covered by any other drinking water supply company. Water is distributed to different properties through actions managed by the community's associations of property owners, which are non-profit institutions governed by Law 19418 and complementary statutes and regulations, taking responsibility for representation, construction, and maintenance of infrastructure to permit the equitable distribution of water resources obtained from Aguas Andinas, or any other inflow replacing this supply if and when it is not available.

The water that we are supplied is dependent on production, and governed by an agreement signed in 1988 between EMOS (now Aguas Andinas) and the community of El Manzano, which agrees the supply of

100 m³ per day, delivered at a large scale water meter maintained by the company among the water intakes that it possesses in the El Manzano Stream; this supply agreement is subject to total suspension for several days at a time, during any period of the year, when water exhibits turbidity, or in the event of emergencies or any other event seen by the company as good cause to suspend service.

The shortfall in drinking water is made up by making use of a proportion of the end user water rights held by members of the association of property owners and normally used for land irrigation, organized by the El Manzano Channel Water Community; this causes serious individual infrastructure costs, in order to permit this irrigation water to be decanted, collected, and chlorinated so that it can safely be used, without risks to families consuming it, and in accordance with universal practices recommended for similar cases.

To date, 324 land owners are members of the drinking water distribution system association, and 91 land owners have yet to join the system, in a land area of 292 hectares - all directly or indirectly supplying our homes with the 100 m³ of water supplied to us each day by Aguas Andinas, and using part of the end user water rights that we hold over water from the Colorado River. This quantity will rise by 885% during the next three five-year periods, due to the implementation of the District Master Plan, which authorizes a considerable expansion in our settlement's population - which will still be supplied with drinking water using the same system.

Thematic responses

Specific response

The Project Owner reiterates its commitment to ensuring that necessary infrastructure exists in the river to permit water to enter the channels at all times, in accordance with the rights granted and the availability of the river throughout the life of the PHAM project.

In conformity with commitments made in meetings held with the management of the El Manzano Channel at the offices of Gener between January and October 2008, Gener has agreed to underwrite the construction of new infrastructure necessary in order to ensure water capture from the Colorado River to which that community possesses legally granted rights, as well as to pay all additional maintenance costs that the community may incur as a consequence of the operation of the PHAM. Furthermore, Gener will pay all additional costs payable by the community to the DGA for corresponding permit applications.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see **Table 2.3.4** in **Chapter 2 of the EIS**.

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that it, in the first section of the river - are fed from intakes located near the Sirena

Channel intake, located approximately 4.5 km upstream of the

Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02 "Hanging" **channels**

Gener has repeatedly issued declarations that it is aware that not only the works that it shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

AGU.04.02 **Maximum flow rates to be abstracted**

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.03 **Ecological flow rates**

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally

complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

AGU.05 Drinking water supply

Construction works and/or activities involved in the project (roads, movement of materials, transport of different products, etc) shall have no effect or impact whatsoever on the quality or security/safety of water supply in the Maipo River system. During the construction phase, Project interventions affecting watercourses shall cause only temporary effects resulting from Earth moving during excavation and other construction activities. This intervention shall affect small areas over short time periods, as it shall last only during the period while these installations are under construction (see **Section 6.4.1.4 of the EIS and Section VII, Question 17, in the Addendum**).

During operations, the PHAM shall not affect the Laguna Negra-Lo Encañado and El Yeso Reservoir system, which is managed by the company Aguas Andinas S.A, in its capacity as holder of the drinking water concession for Santiago; nor shall the Project affect the operational dynamics of the drinking water supply system. Therefore, the implementation of the PHAM does not imply any impact whatsoever on the supply of drinking water (see **Section I, responses 27 and 29, in the Addendum**).

Furthermore, the water abstracted by the Project shall be returned to the river 5 km upstream of the Toma Independiente or Independent Intake, operated by the company Aguas Andinas S.A., which abstracts water for drinking water supply to the city of Santiago; therefore, the PHAM shall not affect normal operations of this system. The PHAM shall only affect the delivery point of water in the tributaries of the Maipo River; in other words, water that currently does not drain into the Maipo River shall not be incorporated into that river's total flow.

However, in the event that an incident may arise as a result of an accident during construction, such as accidental spillages or rock falls, the procedures described in the Contingency Plan shall be implemented, consisting of a suite of actions to solve associated problems. This plan is explained in detail in **Chapter 7 of the EIS, Section 7.2.5**.

AGU.05.01 Drinking water quality

The process of hydroelectric power generation does not affect the physical/chemical qualities of water. Additionally, the PHAM does not plan to implement regulation installations that retain sediment. Thirdly, downstream of the discharge point the natural river conditions are maintained with regard to flow rate and physical/chemical properties.

During the construction of installations to be located in watercourses, the free-flowing course of the river is maintained through the construction of diversions through pipes laid along the river course for such purposes, or through channels that divert all flow, allowing free water circulation with no effect whatsoever on quality (see **Section I, Question 28, in the Addendum**).

The Project owner shall not make use of the Lo Encañado Lake or water usage rights owned by Aguas Andinas S.A. for this Project, instead opting to forgo usage of these resources and to replace the role that would have been fulfilled by the Lo Encañado Lake with a forebay located on a widening of the Alfalfal II plant headworks, located in the Alto Aucayes area on the Colorado River Valley (for details, see **EIS 2.2.1**). The Lo Encañado area shall be assigned a status of controlled access area at all times: it shall not be subject to any intervention whatsoever.

The Project Owner has made available a Water Quality Monitoring Program, with specifications for application during both the construction and operations phases. This program espouses a commitment to verify the effectiveness of environmental control measures designed to minimize the effects of works construction activities during the construction phase.

For further information on the Monitoring Program, see **Sections 8.2 and 8.3 in Chapter 8 of the EIS**.

Remark N° 197 Colorado River Sedimentation Study

No sedimentation study is included applying to the Colorado River. In view of the considerable drop in flow rate in this watercourse, and the discharge of the forebays and sand traps of the Alfalfal, Alfalfal II, and Las Lajas Power Plants, which will empty all sand, silt, and sediment built up during the decantation and storage of water into this watercourse, there will be direct effects on the decantation, clarification, storage, and chlorination structures used to treat our irrigation water to permit risk-free use as drinking water, in compliance with universal practices recommended for similar cases.

A sedimentation study should be presented that will permit the increase in sand, silt, and sediment carried in the water of this river to be gauged. Additionally, please consider economic compensation for this case, in consideration of the harm that will be caused to our decantation, clarification, storage, and chlorination infrastructure, used in the exercise of our end user water rights over water abstracted from the El Manzano Channel Intake

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfal Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This

explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is

- greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (AGU.06.01), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity. Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence. Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted. It can be concluded that the Maipo River system can be managed such that, With the Project operational, present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them. Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

AGU.06.04 Discharge effects

Water capture in advance of in-situ gravel removal leads first to a reduction in sediment load in water carried through the headworks to the turbine rooms, while the solid materials that is retained is returned to the river. At the point where water is discharged from the plants (Las Lajas area), water that has passed through the turbines - which contains a certain quantity of sediment - once again mixes with the water in the rivers, returning to its original conditions in terms of average sediment load (**Addendum, Section I, Question 28**). At the point where water is returned to the Maipo River, in the Las Lajas area, there will be no degradation of the riverbed as it is composed entirely of rocks. It should be mentioned that the flow rate discharged from the PHAM at this point is always lower than the flow rate in the Maipo River just upstream. During the operations phase of the Project, planned maintenance activities do not include any cleaning of tunnels and culverts. Inside the tunnels, the cross sectional area for water flow is small enough to prevent sedimentation. This is shown through the operation of the Alfalfa Plant for 20 years without any cleaning of the tunnels being included among maintenance activities. The only operations that lead to the discharge of sediment are the discharge of gravel traps at the inlets, and the flushing of the sand traps, returning sediment to the river once a certain volume has built up within them. These operations are conducted intermittently and for short time periods (1 minute for sand traps, 10 minutes for gravel traps), at variable frequency depending on the season. For more information see the **Addendum, Section IV, Question 3**.

PRO.01.01 Compensation

The concept of compensation refers to the act of indemnifying damages or harm caused. Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS). In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district. In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district. During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on

mountain sports tourism is available in Annex 35 of the EIS,
"Complementary survey of tourist attractions and tourism services

in the District of San José de Maipo”, and Annex 36 of the EIS, “Survey of high mountain activities”.

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. The study also investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 198 Effects on Water Quality in the Colorado River

In view of the considerable drop in flow rate (up to 12 m³/s) and the increase in sand, silt, and sediment load, the current **physical/chemical, biological, and acidity characteristics of the water will be affected.**

A study should be presented permitting understanding of whether the water will suffer variations in its **physical/chemical, biological, and acidity characteristics**, such that it may be used risk-free, under the parameters of universal practices recommended for similar cases; additionally, please consider **economic compensation for this case, in consideration of the harm that will be caused to our decantation, clarification, and storage infrastructure, used in the exercise of our end user water rights over water abstracted from the El Manzano Channel Intake.**

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum.**

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing

less than 30% of sediment deposited in that zone.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water,

which will pass through the turbines and then be returned to the river. This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.01.01 Compensation

The concept of compensation refers to the act of indemnifying damages or harm caused.

Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS).

In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

SOC Socio-Economic Impact

Job creation plans for the district will take into account the concerns expressed by community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. The study also investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

Remark N° 199 Effects on Sedimentation Volume due to Actions at Forebays and Sand Traps

Given that the quantity of water to be used in operating discharge spillways into the Colorado River, or the quantity of material and sediment that will build up in the forebay and sand traps of the Alfalfal, Alfalfal II, and Las Lajas Plants, for which rights exist, for maximum periods of 15 minutes 6 times per day, these should be added to the 12 m³/s excess in the river, and the Colorado River will therefore suffer permanent changes in its sedimentological volume (mass and volume, which will result in extreme size and force with no control) flowing into the river, considerably adding to risks affecting the structures of the El Manzano Channel Intake, which is located downstream of these plants.

Economic compensation should be agreed relating to this effect, to cover damage that may be caused to the El Manzano Channel Intake structures by these effects.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfal Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.04 Discharge effects

Water capture in advance of in-situ gravel removal leads first to a reduction in sediment load in water carried through the headworks to the turbine rooms, while the solid materials that is retained is returned to the river. At the point where water is discharged from the plants (Las Lajas area), water that has passed through the turbines - which contains a certain quantity of sediment - once again mixes with the water in the rivers, returning to its original conditions in terms of average sediment load (**Addendum, Section I, Question 28**).

At the point where water is returned to the Maipo River, in the Las Lajas area, there will be no degradation of the riverbed as it is composed entirely of rocks. It should be mentioned that the flow rate discharged from the PHAM at this point is always lower than the flow rate in the Maipo River just upstream.

During the operations phase of the Project, planned maintenance activities do not include any cleaning of tunnels and culverts. Inside the tunnels, the cross sectional area for water flow is small enough to prevent sedimentation. This is shown through the operation of the Alfalfal Plant for 20 years without any cleaning of the tunnels being included among maintenance activities. The only operations that lead to the discharge of sediment are the discharge of gravel traps at the inlets, and the flushing of the sand traps, returning sediment to the river once a certain volume has built up within them. These operations are conducted intermittently and for short time periods (1 minute for sand traps, 10 minutes for gravel traps), at variable frequency depending on the season. For more information see the **Addendum, Section IV, Question 3**.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature

no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned

to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic. The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly

frequented, minimizing their visual impact.

PRO.01 Regulations

A plan has been prepared addressing compliance with environmental regulation legislation applicable to the Project, as stipulated and specified in Article 12 part g) of Law 19,300, and Article 12 part d) of Ministry of the General Secretariat of the Presidency of the Republic Supreme Decree 95.01, which sets the recast text of the Regulations on the Environmental Impact Evaluation System (RSEIA), indicating the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and the sector environmental permits that the Project will require for its execution (EIS, Chapter 3, Section 3.1)

Chapter 3 of the EIS provides detailed information on:

- The legal framework within which the Project was designed;
- The oversight bodies tasked with enforcing compliance in matters subject to regulation;
- The ways in which the Project will ensure compliance with these regulations.

The Project Owner is obligated to comply strictly with legislation in force, and the bodies tasked with enforcing this compliance are the governmental and state bodies specified in the same legislation.

PRO.01.01 Compensation

The concept of compensation refers to the act of indemnifying damages or harm caused. Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS).

In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

Remark N° 200

Maintenance Program and Emergency Plan

No maintenance program (annual, every five years, etc.) is presented for the Alfalfal II and Las Lajas Plants, or the Las Lajas discharge spillway. Similarly, no emergency plan is presented, for activation in the event of a situation giving rise to a need to shut down the plants or the tunnel.

A maintenance plan and an emergency plan should be attached, providing information on the volume of water to be discharged into the river, and guaranteeing the prevention of damage to structures, buildings, or persons who may be present, or who work in the Colorado River downstream of the discharge point, specifying the measures taken to prevent and mitigate possible emergency situations.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

RSG Risk

The Project Owner possesses a general risk prevention strategy that imposes certain measures on the Project during its different stages of advance. This strategy features the following components:

- a) Measures incorporated into the Project's engineering design.
- b) Systematic verification of compliance with applicable regulations c) Establishment of restricted areas
 - c.1) Area restricted due to their archeological, paleontological, or heritage value
 - c.2) Area of natural value that requires protection by the Project
 - c.3) Officially protected area.
- d) Expert supervision during construction
- e) Training regarding environmentally sensitive issues
- f) Internal risk management and accident prevention programs g) Separation of works installations and encampments

For further information on each of these points, please see **Chapter 7 of the EIS**, which specifies the **Environmental Management Plan**, the **Risk Control and Prevention Plan** designed for the Project, the safety measures to be adopted in light of the risks identified, and, finally, the **Accident control plan**, to be activated in the event of the failure of the preventive measures taken by the Project Owner. Furthermore, **Annex 32 of the EIS** presents the **Risk and Contingency Prevention Plan** for contractors.

RSG.01 Load rejection

During the operation of the power plants, situations may arise that necessitate the stoppage of one or both plants for a certain period of time. Two temporary phenomena occur at such times, the effects of which must be analyzed. These phenomena are mass oscillations within tunnels carrying water under pressure, and impact on the Maipo River system's flow dynamics.

A special situation arises in the operation of a hydroelectric plant when a sudden stoppage occurs affecting its power generation units or discharge spillways. Load rejection can arise as a result of automatic shutoffs caused by internal or external failures:

- Internal. These situations relate to technical problems within the power plant that require the stoppage of the turbines. This can arise due to a mechanical failure (valve or turbine failure) or an electrical fault in the mechanisms that operate the generator units, or in the high tension switchgear (switches or power line distributors).
- External. External events can lead to total system failure (black out), which is a less frequent situation. This can be caused by a break in the power transmission line that serves both power plants.

Fortunately, such events are infrequent; by way of illustration, see **EIS Annex 17, Table 3.1**, which shows a summary of load rejections that occurred at the Alfalfal Power Plant from 2004 to 2007.

For further information on the analyses taken into account for different potential cases of failures in the power generation units in the Alto Maipo plants, please see **Annex 17 of the EIS and Annex 16 of Addendum 1**.

Remark N° 201 Guarantee Regarding Complementary Works Related to the Project

No guarantee is presented regarding the permanent protection of complementary works to be constructed on the **El Manzano Channel**, defined by AES Gener as **SEMI - PERMANENT WORKS** and which will require periodic maintenance and repair.

It should be born in mind that water and water flow are produced by natural effects, and similarly that all effects that arise in watercourses - rock falls, tree falls, stones and rocks, sandbanks, stagnation of waste matter and trash, and deterioration of works installed in the watercourse - are effects attributable to the nature and volume of the water flowing through the river. Engineering installations built in rivers' watercourses can only be obstructed, damaged, or destroyed as a result of the natural effects of the volume and power of water flow.

The Project Owner should expressly agree a compensatory guarantee payable in the event of any situation that impedes the normal abstraction of water under our 16 irrigation rights, permitting 100% coverage of economic aid necessary for maintenance and repair costs affecting the complementary works on the El Manzano Channel for as long as the hydroelectric plants remain operational. This compensatory guarantee shall not be payable in the case of damage caused by earthquakes or catastrophes, as defined by a decree issued by the competent state body.

Thematic responses

Specific response

The Project Owner reiterates its commitment to ensuring that necessary infrastructure exists in the river to permit water to enter the channels at all times, in accordance with the rights granted and the availability of the river throughout the life of the PHAM project.

In conformity with commitments made in meetings held with the management of the El Manzano Channel at the offices of Gener between January and October 2008, Gener has agreed to underwrite the construction of new infrastructure necessary in order to ensure water capture from the Colorado River to which that community possesses legally granted rights, as well as to pay all additional maintenance costs that the community may incur as a consequence of the operation of the PHAM. Furthermore, Gener will pay all additional costs payable by the community to the DGA for corresponding permit applications.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in
**Chapter 2 of the
EIS.**

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that it, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988),

with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02 **“Hanging”** **channels**

Gener has repeatedly issued declarations that it is aware that not only the works that it shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

PRO.01.01 Compensation

The concept of compensation refers to the act of indemnifying damages or harm caused. Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS).

In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

Remark N° 202 Guarantee over End User Water Rights

No permanent guarantee is planned covering usage of the 16 irrigation end user water usage rights held by the users of the El Manzano Channel and abstracted through the intake of that channel.

A compensatory guarantee should be agreed, with payments to be made for each day that 100% of the water over which we hold rights is unable to enter the El Manzano Channel Intake, for any reason. This compensatory guarantee shall not be payable in the case of downtime caused by earthquakes or catastrophes, as defined by a decree issued by the competent state body.

Thematic responses

Specific response

The Project Owner reiterates its commitment to ensuring that necessary infrastructure exists in the river to permit water to enter the channels at all times, in accordance with the rights granted and the availability of the river throughout the life of the PHAM project.

In conformity with commitments made in meetings held with the management of the El Manzano Channel at the offices of Gener between January and October 2008, Gener has agreed to underwrite the construction of new infrastructure necessary in order to ensure water capture from the Colorado River to which that community possesses legally granted rights, as well as to pay all additional maintenance costs that the community may incur as a consequence of the operation of the PHAM. Furthermore, Gener will pay all additional costs payable by the community to the DGA for corresponding permit applications.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4**

in Chapter 2 of the EIS.

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that is, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02 "Hanging" channels

Gener has repeatedly issued declarations that it is aware that not only the works that it shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights

held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.04 Monitoring and control of flow rates and water levels

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate (Qe) approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum.**

The principal environmental protection measure planned for watercourses subject to intervention under the PHAM consists of maintaining an ecological flow rate approved by the DGA. In the case of the PHAM, the analysis of Qe has taken into account not only hydrological variables but also biological information necessary to preserve the aquatic organisms associated with the watercourses.

Ecological flow rates will be maintained in rivers and streams, including those that are currently subject to artificial flow regulation and those that currently maintain natural flow dynamics. This multipurpose measure will minimize impact on the landscape that would be associated with flow reductions, principally in areas with greater visual accessibility (**Addendum, Section 5, Question 2**).

The Project Owner plans to undertake continuous and permanent measurement of ecological flow rates throughout the useful life of the project.

For this purpose, 4 stream gauge stations and 6 control stations will be installed, at the locations specified in the following table:

Sector	Station	Coordinates (UTM)	
		Easting	Northing
	Alto Volcán		
	Stream gauge station		
	406,157		6,259,100
	La Engorda Stream Bridge		
Alto Volcán	Rain gauge station	460,487	6,358,143
	El Volcán River Bridge (Volcán South)		
Alto Volcán	Control station	407,468	6,259,751
	La Engorda Intake		
Alto Volcán	Control station	406,780	6,260,782
	Las Placas Intake		
Alto Volcán	Control station	407,181	6,260,081
	Colina Intake		
Alto Volcán	Control station	405,768	6,261,231
	El Morado Intake		
Yeso River	Rain gauge station	391,504	6,262,449
	PBN (15)		
Yeso River	Control station	399,666	6,272,077
	El Yeso Intake		
Colorado River	Rain gauge station	380,449	6,287,261
	El Sauce		
Colorado River	Intake control station	389,063	6,292,501
	Colorado River		

With regard to water quality, measurements have been taken along the watercourses involved in the PHAM (see details in **Chapter 5, Section 5.3.5.2**), and an Environmental Monitoring Plan has been drawn up, featuring actions related to maintaining water quality and mitigating potential impacts on tributaries (**EIS, Chapter 7, Section 7.1 and Chapter 8, Section 8.2.3**).

For more information, see **Annex 17 of the Addendum.**

PRO.01 Regulations

A plan has been prepared addressing compliance with environmental regulation legislation applicable to the Project, as stipulated and specified in Article 12 part g) of Law 19,300, and Article 12 part d) of Ministry of the General Secretariat of the Presidency of the Republic Supreme Decree 95.01, which sets the recast text of the Regulations on the Environmental Impact Evaluation System

(RSEIA), indicating the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and the sector environmental permits that the Project will require for its execution (EIS, Chapter 3, Section 3.1)

Chapter 3 of the EIS provides detailed information on:

- The legal framework within which the Project was designed;

- The oversight bodies tasked with enforcing compliance in matters subject to regulation;
 - The ways in which the Project will ensure compliance with these regulations.
- The Project Owner is obligated to comply strictly with legislation in force, and the bodies tasked with enforcing this compliance are the governmental and state bodies specified in the same legislation.

PRO.01.01 Compensation

The concept of compensation refers to the act of indemnifying damages or harm caused. Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS).

In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

Remark N° 203

Sedimentation: soils and other irrigation structures

No consideration is made regarding the rapid sedimentation that will affect our soils through increases in levels of sand, silt, and other particles carried in our irrigation water, as abstracted from the Colorado River at the El Manzano Channel Intake, settling out in all of our irrigation structures and finally being deposited in our soil - leading to a wide range of problems, such as the blockage or partial blockage of irrigation channels, increases in cleaning costs, reduction in the inherent qualities of agricultural and non-agricultural soils, and other problems that are difficult to classify.

For this reason, a study should be presented evaluating sedimentation across the 292 hectares of land area and the associated irrigation infrastructure that uses water drawn directly from the Colorado River, resulting from increases in levels of sand, silt, and other particles in water running through the El Manzano Channel. Additionally, compensation should be defined corresponding to these effects.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4 in Chapter 2 of the EIS.**

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that is, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02 "Hanging" channels

Gener has repeatedly issued declarations that it is aware that not only the works that it shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum.**

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders

of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and

design" (**Chapter 6.1 of the Sedimentation Study** presented in **Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (**AGU.06.01**), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted.

It can be concluded that the Maipo River system can be managed such that, With the Project operational, present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

PRO.01 Regulations

A plan has been prepared addressing compliance with environmental regulation legislation applicable to the Project, as stipulated and specified in Article 12 part g) of Law 19,300, and Article 12 part d) of Ministry of the General Secretariat of the Presidency of the Republic Supreme Decree 95.01, which sets the recast text of the Regulations on the Environmental Impact Evaluation System (RSEIA), indicating the general and specific regulations directly associated with protecting the environment, preserving nature, the usage and management of natural resources, and the sector

environmental permits that the Project will require for its execution (EIS, Chapter 3, Section 3.1)

Chapter 3 of the EIS provides detailed information on:

- The legal framework within which the Project was designed;
- The oversight bodies tasked with enforcing compliance in matters subject to regulation;
- The ways in which the Project will ensure compliance with these regulations.

The Project Owner is obligated to comply strictly with legislation in force, and the bodies tasked with enforcing this compliance are the governmental and state bodies specified in the same legislation.

PRO.01.01 Compensation

The concept of compensation refers to the act of indemnifying damages or harm caused. Within the framework of the EIS, the Project Owner has issued a proposal to the competent authority regarding a suite of environmental management measures aiming to minimize, compensate, and restore the Project's impacts, making their implementation sustainable (Chapter 6 of the EIS).

In this regard, compensation is understood to be included in the spirit or end goal of the environmental management measures proposed by the Project Owner, following the evaluation of the direct and indirect effects of the PHAM on each of the environmental components stipulated in Supreme Decree 95, SEIA Regulations.

Remark N° 204 Loss of Fiscal Holdings

No consideration is given to the loss of fiscal holdings arising through reductions in river and stream flow rates and soil moisture levels caused by the project.

Economic compensation should be agreed, covering the costs of incorporating other spaces into municipal fiscal property holdings, for use in the service of the public at large. E.g. Acquisition and installation of viewpoints along the banks of the Maipo River.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical

variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

ARQ Archeological and Paleontological Sites: Heritage

According to the results of archeological survey activities and background information compiled, the Project's area of influence features two more sensitive areas, which contain resources of cultural interest. These sites are located in the Project's area of **indirect influence**; they are locations where no PHAM construction is scheduled to take place. These sites are:

- Lo Encañado Lake area, where two sites of archeological interest have been recorded (Las Morrenas and Camino del Inka)
- Colorado River – Aucayes Stream area, where the site known as Aucayes 1 was recorded.

For more information, see **Annex 9 of the EIS**. Meanwhile, information on paleontological finds is included in **Annex 14 of the Addendum**.

ARQ.02 Values preservation

General paleontological protection measures:

i) Restricted area applicable to contractor company employees

This restriction will apply to the area adjacent to the Alto Volcán sector, where PHAM construction is to take place, known as the Valle de las Arenas. The Project Owner will declare this area a "restricted zone" with regard to the contractors (see the map included in Annex 14 of the Addendum); contractor personnel will have their access restricted, and permanent or temporary construction activities will be prohibited (section 6.3.3 of the EIS). This area will be marked out with clear signage, applicable to all Contractor personnel during the construction phase.

ii) Delimitation of buffer zones

Before the start of construction activities, a team of professional paleontologists will conduct an inspection visit and will delimit the areas that are of paleontological interest (e.g. concentrations of Río Damas Formation blocks, which contain possible traces of prehistoric vertebrates). A buffer zone will be laid out around each such area, installing signage centered on the prohibition of access, as a means of preventing accidental damage to items of interest by contractor company personnel or private individuals passing through the area. This measure implies a commitment by the contractors to enforce compliance with the access restriction.

The Project Owner shall take the decision to fence off areas of paleontological or archeological interest as required, avoiding negative impacts.

iii) Contingency measures

In the event that fossil materials are found in other areas, the National Monuments Council will be notified, and the team of paleontologists engaged in the Project's paleontological monitoring shall assess procedures that must be undertaken, in accordance with the stipulations of Law 17,288 and accompanying regulations.

iv) Compensation measures

- a) production of cultural information material**
- b) creation of a viewpoint**
- c) fossil trail**

For more information and details on the preservation of heritage value and paleontological resources, please see **Annex 14 of Addendum 1**.

Remark N° 205

Law 19300, General environmental base law, TITLE I, Article 2. "for all legal purposes it should be understood that"...

Environmental damage [is] any significant loss, decline, detriment, or harm caused to the environment, or to one or more of its components.

Environmental Impact Study: A document that provides point by point details of the characteristics of a project or activity planned to be implemented or modified.

It should provide documented background information that can be used to predict, identify, and interpret its environmental impact and describe the action or actions that it shall take in order to prevent or minimize all significant adverse effects.

Environmental impact: alteration of the environment, directly or indirectly caused by a project or activity in a specific area.

Reparation: the act of returning the environment, or one or more of its components, to a state similar to that in which it was to be found before damage caused, or, if this is not possible, the re-establishment of its basic properties.

Article 3. Notwithstanding the sanctions stipulated by law, any person or body that through action or gross negligence causes damage to the environment shall be obliged to make full material reparations, at its own expense, if possible, and to provide compensation as stipulated by law.

Both of the parties (Eduardo Atisha Carrasco as the party affected by water abstraction, and the PHAM owned by AES Gener as the other parties) are aware of the following points. AES Gener holds water rights. Eduardo Atisha Carrasco is the owner of a project approved by the ORD. Ministry of Public Works Document 3238, dated November 07, 1997, issued by the Metropolitan Regional Highways Department. The highways department has approved the installation of a sand trap in the Maipo River, for water decantation, diverting some of the river's flow and channeling it through a sand sedimentation installation to settle out material carried in suspension or dragged along the riverbed, which installation was built and installed in the Maipo River valley, adjacent to the property that I own located at Camino al Volcán N° 22705, District of San José de Maipo; this concession over the usage of an item of national property of public usage for the construction and usage, in accordance with a project plan approved by the River Defense Department, of an aggregates separation facility in the Maipo River, where activities relating to the extraction of aggregates are conducted using mechanized techniques, using for these purposes a truck and a front loader, approved on December 3, 1997. In view thereof, I am the holder of a right that I acquired more than a decade ago.

Therefore:

Under the supposition that the maximum flow rate generated by the project corresponds to the design flow rates of the plants - the Alfalfal II plant, with 27 m /s and the Las Lajas Plant with 65 m /s - this water being sourced from the PHAM's headworks intake system. The sum total design flow rate is calculated to be 69.8 m /s.

Point	Maximum design flow rate calculated in
Colina Stream	6
Las Placas Stream	1
El Morado Stream	3.7
La Engorda Stream	2.1
Yeso River	15
Aucayes Stream	2
Colorado River at Alfalfal	30
Colorado River at Maitenes	10

Question 1: Why is the design flow rate exceeded? Merely from the paragraph shown above (quoted directly from the project presentation in chapter 2.3.20), it is clear that the sum of the Alfalfal II and Las Lajas plants' flow rates is 65 m/s, and excess water will be returned to the watercourses; but how am I to know that the water that the PHAM claims to abstract for energy generation will not be the maximum design flow rate thus calculated?

This flow rate is certainly greater than the 4.8 m/s declared for the intake. What is the real input flow rate? I would also like to ask what you are talking about in Annex 20 of the Project. In the Maipo River Sedimentation Study.

1. Summary and conclusions.

Project impact on the system's sedimentation equilibrium...

In view of the absence of integrated management plans for aggregates extraction activities in the Maipo River, annual extraction rates appear to stand at the very limit of the what is sustainable for the watercourse, as deduced for background information reviewed. In this scenario, any perturbation to the system could lead to local riverbed erosion problems, as has occurred in the past due to overextraction during certain periods. Therefore, if the predicted reductions in sediment availability downstream of the Independent Intake implemented by the project come to pass, then although these variations are relatively minor, they may lead to local problems if measures are not taken to ensure more rational management of the watercourse and available water and aggregates resources. This management should clearly be conducted addressing the river basin as a whole, implemented by the competent authority.

It must be born in mind that whether or not the project goes ahead, in the long term the effects of the dam on the El Yeso River will come to be felt, leading to a state of static shielding, preventing this watercourse from contributing any significant quantity of sediment. This results in an estimated reduction of between 0.2 and 0.5 million tons per year in riverbed erosion and entrainment, for the situation without the current project. It is hard to estimate when this effect will be observed, particularly bearing in mind that after 43 years of operation of the dam, there is as yet no significant evidence of the formation of static shielding.

Finally, it should be mentioned that the morphological conditions of the Maipo River at the point where it leaves the valley are a consequence of the natural reduction in its sediment transport capacity, leading to the deposition of a proportion of its sediment load and the formation of multiple watercourses and islands. In view of its characteristics, the Maipo River (and all of the rivers not subject to intervention, in general) is not static, but rather

continually evolving, in a dynamic equilibrium where in flow rate, sedimentation, and river morphology are permanently interacting and modifying each other. The rate at which the system changes may be altered (and accelerated) if it

sediment transport rates into the system are changed, or in the event of excessive extraction of aggregates from the river, water flow may eventually lead to degradation in certain parts of the river system. However, these effects may be reduced or controlled through suitable management of the system; such management must necessarily be based on integrated perspective, including the entire river system through to the river mouth. In this sense, it can easily be seen that at present no rational management system is applied to the extraction of aggregates in the Maipo River System. When the competent authority grants extraction permits based on local criteria, it fails to take into account the reaction of the system, in both spatial and temporal terms, and movement towards a new equilibrium situation.

Question 2: On what grounds does the competent authority take the decision to grant permits based on local criteria? Does this refer to the criteria applied by the Metropolitan Regional Highways Department, now the Hydraulic Works Department? Or the criteria applied by the Mayor of San José de Maipo? Or do the criteria applied by the Municipal Council take precedence? Or the criteria that should now be applied by CONAMA, under Article 2 of Supreme Decree 95/2001?

Total watercourse erosion and entrainment with the Project operational
The watercourses affected by the project, which will be subject to a drop in transport of sediment in suspension into the Maipo River, are the Volcán, Yeso, and Colorado Rivers. The reduction in the value of solid streambed particle entrainment in the rivers is estimated at 0.05, 0.03, and 0.09 millions of tons per year. The total reduction associated with the project is of the order of 1 million tons per year, representing almost 30% of the predicted value for solid streambed particle entrainment in the Maipo River at Las Vertientes in the absence of the project. The predicted value for solid streambed particle entrainment in the Maipo area at Las Vertientes with the project operational, meanwhile, will be reduced by approximately 2.0 million tons. Adding together the predicted values for solid particle entrainment and suspension particle entrainment, for the situation with the project operational, one obtains a value of approximately 9.6 million tons per year, representing 78% of the value - 12.3 million tons per year - estimated for the situation without the project (that is, a reduction of 22%).

Question 3:

All of this is without having conducted studies in the San José de Maipo or Manzano areas. However, the total value for the sand production industry at El Manzano is known, as the study published by R.E.G. Ingenieros specifies a total of 3 million tons per year.

Subtracting the declared value of the PHAM from this real and serious value, the expected value for solid streambed particle entrainment in the Maipo area at Las Vertientes with the project operational, meanwhile, will be reduced by approximately 2.0 million tons. I am talking about 66.6% less total particle wear and entrainment (including streambed and suspension sedimentology).

Most sediments are transported not in suspension, but rather dragged along the streambed. Therefore, if you take 27.8 cubic meters of water sourced from the 4 streams emptying into the Volcán River, plus water captured from the Yeso River, this is equivalent to 5 times more at the level of San José del Maipo than at the start.

What I want to explain to you in simple terms... Imagine a snowball. If you set it rolling over the snow, it gets bigger in volume until it forms a very large ball. Well, water in the river is the same. The cubic meter that you capture in the Upper Volcán Basin, by the time it gets, for example, to San José de Maipo, is no longer equivalent to a cubic meter; instead, it is equivalent to five cubic meters, at least as it is now carrying rocks, gravel, and sand. This factor is a result of the friction or grinding of the larger rocks that strike against each other, making ever smaller rocks, then gravel, and finally sand. This cycle or mechanism functions if and only if the river has water in it. Do you understand the natural mechanism that underpins the natural law of a watercourse? A sand man like me, with a mechanized extraction technique that only extracts sand during the ice melt season, from November 21 to the first two weeks of February, with the time in December between Christmas and New Year being my most productive season.

Finally, the factor that plays a stabilizing role in the evolution of this watercourse is the natural sedimentation slope gradient, which is unique for each river course like the Maipo River, and forms itself naturally depending on the water flow rate during the flood season in the watercourse, solid streambed particle entrainment and streambed transport granulometry, also naturally forming a particular watercourse width depending on the same factors (Flow Dynamics Theory). In this way, alluvial watercourses naturally form their own stable slope gradient and width, such that total annual sedimentation load brought down to the valley from the high mountains finally reaches the sea, after additional grinding during transport. The slope gradient increases over time, just as the size of particle transported and the width increase as the flow speed in the watercourse declines.

It is this very stability that can be altered by artificial installations. This then leads to a new sedimentation equilibrium slope gradient, and this must therefore be subject to analysis by the PHAM. It is certain that such a "study" relies on very different principles to the documentation presented.

According to the information that you yourselves put forward in Annex 20.

Survey Campaign.

Four survey visits were conducted in the Cajón del Maipo study area - two in September, the third in October, and the final visit in November 2007. These survey studies visited the different stretches of watercourses of interest, running from the Volcán River near the site where the Project's intakes will be installed in the La Engorda Valley, through the Maipo River upstream of the mouth of the Volcán River, to the Yeso River, as well as the Las Vertientes area and the Colorado River between the Maitenes intake and the junction of that river with the Maipo River. Due to heavy snow drifts, during the month of September it was not possible to reach the area where the La Engorda Valley, Colina Stream, and Morado River intakes are to be sited - it was for this reason that it was necessary to make the fourth visit, in November. The October survey visit was conducted together with an external company that conducted topographic and bathymetric surveys in sites selected during previous field visits. The purpose of these field campaigns,

above and beyond gaining a perspective on the study area, was to define the areas where topographic and bathymetric surveys would be necessary, the locations of exploratory trenches, water sediment sampling, and measurements of surface granulometry.

Question 4:

Therefore, please do not talk about four views. There were only three, and you counted wrong because

if it had not been for the snow, as you yourselves admitted, you would not have visited the area in November.

In any event, measurements of this type must be taken between November and February. This is the season when the winter snows melt, and therefore it is at that time that the rivers carry the highest loads of suspended sediment, and studies to determine surface granulometry.

No studies exist regarding San José de Maipo. No records of sediment in suspension exist regarding San José de Maipo.

According to the study by R.E.G. Ingenieros. Mountain foothill sector, from km 190 to km 159: this stretch of the Maipo River, from the Yeso River to the San Carlos Channel Intake, features a narrow watercourse measuring around 100 m in width, well dug into the alluvial and colluvial terraces at the bottom of this mountain foothill valley. It has an average slope gradient of $i = 0.87\%$ formed from a series of whitewater rapids and slow-flowing pools, which exist as a result of massive colluvial blocks of over 5 tons located on the riverbed. Despite the impact of the landslides that occurred in 1987 and 1993, this stretch of the river has remained in the same course since 1979.

Total streambed erosion with the Project operational

Coarse sediment transport from the upper reaches of the Volcán River into the Maipo River currently occurs at a very low level, and this will suffer no significant variation under the project. Sediment transport into the Maipo River from the Yeso and Colorado Rivers will be affected by the project. Sediment transport into the Maipo River from the Yeso and Colorado Rivers will be affected by the project. Under the least favorable calculation model, a reduction of the order of 0.2 to 0.5 million tons per year can be expected in the predicted values for transport from Yeso River, and of the order of

1.4 to 1.8 tons per year in the expected values for transport from the Colorado River, such that the total reduction in expected values for solid streambed erosion in the Maipo area at Las Vertientes is of the order of 2 million tons per year, or equivalent to approximately 22% of the 8.9 million tons per year estimated under the situation without the project.

It then states... The project will not modify water flow rates downstream of the Independent Intake, and therefore the solid erosion capacity of this area will not be affected. If aggregates extraction rates in the area

Question 5:

Does it not strike you as correct for nobody to express an opinion that you or those who have conducted the studies have massaged the information, that is, they have distorted it only so as to favor what the PHAM proposes. For this to be a professional and serious calculation regarding the Maipo River at Las Vertientes, it should include transport of coarse sediment from the Volcán River, the Yeso River, the Maipo River itself, and the Colorado River. Given that strictly speaking it is these four rivers together that feed into the Maipo River in the area that you yourselves mention. This study was not conducted at San Alfonso, and even less at San José de Maipo - which is where it ought to have been conducted, as this is the site of the only sand decantation facility in the entire district of San José de Maipo, which was completed on September 26, 2000. It is at this point that you ought to have mentioned the input of coarse sediment from the Volcán River, the Yeso River, and the Maipo River itself. Did you know that the DOH bases all of its responses to those in the sand extraction industry on an engineering study that the Ministry of Public Works River Works Department, adopting DGOP Resolution N° 776 dated October 23, 1997, and entered into records on November 07, 1997, assigned to R.E.G. Ingenieros?, Are you aware that this study was conducted in the most serious manner possible, as the Ministry of Public Works commissioned it to be conducted regarding the Maipo River and its tributaries as a source of aggregates to supply the Metropolitan Region, Region V, and Region VI?

The need for this study arose from an analysis of the unfavorable balance that exists comparing estimates for production from the Maipo River Basin and the growing demand that underpins the country's development.

The overexploitation of the watercourses would result in subsidence leading to the undermining of riverside infrastructure such as **Intakes**, channels, and bridges, among others. The specific objectives that establish the Terms of Reference are as follows:

- Analysis of the geological characteristics of the area, identifying the regions that are sources of aggregates and proposing methods to determine their production potential.
 - Preparation of a diagnostic model of aggregates extraction from the perspectives of technical, administrative, and economic considerations.
- Proposition of annual aggregates extraction rates for each stretch of the Maipo River and the tributaries in question, such as to ensure a sustainable extractive industry.
- Proposition of a control methodology and an oversight methodology for the extraction of aggregates.
- Analysis of the benefits of aggregates extraction from natural watercourses for each district, taking into account control measures and oversight financed by the municipal government in question or overexploited watercourses.

Question 6:

Do you consider it to be serious and professional to prejudice the economic activity of thousands of families, specifically including my own family, the family of a sand man, this being a PERMANENT source of employment in San José de Maipo for many families that depend on this activity; should such impacts be taken lightly? While a "study" speaks of data without having taken measurements at the control points that should have been recognized.

The areas that are sources of aggregates in the Maipo River Valley are:

- Olivares River.
- Colorado River.
- Barroso River.
- Maipo River.
- Yeso River.
- Clarillo River.

The analysis commissioned by the Ministry of Public Works concludes that, in the Maipo River at El Manzano, it was possible to determine the source of 90% of total aggregates production in the river basin, during the ice melt season (October to March).

For the period from April to September, the Maipo River at El Manzano transports between 30% and 40% of total aggregates production.

I conclude that the "study" presented in the PHAM EIS, in Annex 20, necessarily underestimates real values.

To extract aggregates from the Maipo River, in my case using a mechanized extraction system located above the average water level in the river, so as to avoid seepage from the water table during aggregates production. This depends absolutely on the river rising above the level of my property, carrying 120 cubic meters per second. This is the starting flow rate for it to be possible for me to extract aggregates.

Therefore, when you capture 27.8 cubic meters per second, my only source of income or economic activity disappears. I base this analysis solely on average flow rate information showing that the month of December will be the only month when I will be able to extract aggregates, truthfully only between Christmas and New Year, which is the period when the river carries 150 cubic meters per second on removal of abstracted flow.

In my particular case, what are the thoughts of the PHAM given that it directly affects my activities?

Ladies and gentlemen, you are perhaps all long standing employees of AES Gener, with one, two, ten, or fifteen years in your jobs. When you retire, are fired, or resign, the company will forget you, you are merely cogs in its machine.

My case is different. I am the owner of this property, I have invested years of work, years sacrificing time and my family to get ahead with this sand bank. Money spent implementing this project, which I began to develop in 1996. I defend what is mine, and what has certainly come at a cost to me and my family; I defend the land that I bought; I defend the only thing that I can leave to my children, my grandchildren, and perhaps my great-grandchildren. I defend the only livelihood in which I know how to WORK on what is mine.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them

into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4 in Chapter 2 of the EIS**.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.06 Sediment**

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study** presented in **Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent

approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of river flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (AGU.06.01), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted.

It can be concluded that the Maipo River system can be managed such that, With the Project operational, present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river.

In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in

flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level.

It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be identical to those currently observed.

It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times of the year flow rate in the Maipo River watercourse drops significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake owned by Aguas Andinas, etc.

Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual abstraction rate at these intakes varies between 78 and 164 m³/second.

This situation clearly explains the high level of perturbation observed in the

behavior of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years.

Remark N° 206

Law 19300, General environmental base law, TITLE I, Article 2. "for all legal purposes it should be understood that"...

Environmental damage [is] any significant loss, decline, detriment, or harm caused to the environment, or to one or more of its components.

Environmental Impact Study: A document that provides point by point details of the characteristics of a project or activity planned to be implemented or modified.

It should provide documented background information that can be used to predict, identify, and interpret its environmental impact and describe the action or actions that it shall take in order to prevent or minimize all significant adverse effects.

Environmental impact: alteration of the environment, **directly or indirectly caused by a project or activity in a specific area.**

Reparation: the act of returning the environment, or one or more of its components, to a state similar to that in which it was to be found before damage caused, or, if this is not possible, the re-establishment of its basic properties.

Article 3: Notwithstanding the sanctions stipulated by law, any person or body that through action or gross negligence causes damage to the environment shall be obliged to make full material reparations, at its own expense, if possible, and to provide compensation as stipulated by law.

- Application of dust suppressant on Route G25 from Romeral to El Yeso 22 Km.
Route G455 from Romeral to Colina 21 Km. Application of bischofite solution (magnesium chloride).

In terms of characteristics, magnesium chloride hexahydrate, or bischofite, is a salt. It possesses a range of properties that permit its potential use as a chemical stabilizer in granular roadways: capacity to absorb and retain water from the surrounding environment, increases in water's surface tension, and reduction in water's vapor pressure. The addition of bischofite permits the creation of a stable roadway, reduces the formation of potholes, corrugation, loss of material, and dust emissions, while improving the driving experience.... **Inorganic stabilizers** include sodium chloride, magnesium chloride hexahydrate, calcium chloride, calcium sulfate, calcium carbonate, phosphoric acid and phosphates, and sodium hydroxide. Disadvantages of the usage of soil stabilizers. The usage of soil stabilizers is restricted by factors relating to soil type and climate conditions. For the soils found in our country, most stabilizers required the addition of fine-grain material, resulting in a disadvantage as against direct application with existing materials.

In terms of the disadvantages of bischofite agents, what is the effect of rainwater runoff from soil treated with bischofite when it makes contact with rivers, streams, springs, groundwater, meadows/wetlands, hot springs, and vegetation, or if animals drink this water after it has been in contact with magnesium chloride?

I request that, in responding to the issue of rainwater, you do not state that bischofite will be applied only in the summer to prevent dust, not in the winter. In the Cajón del Maipo area, it does not only rain during the winter. Rain also falls during the summer months of November, December, January, and February. We are talking about low and high mountain areas, at altitudes of 2000 to 2500 meters.

All of these are present in at least parts of the two stretches of road that will be treated with magnesium chloride.

What is the PM10 or inhalable particulate material? These are particles with diameter equal to or less than 10 microns (a micron is one thousandth of a millimeter). Due to its size, PM10 is capable of entering the human respiratory system. The smaller these particles are, the greater their potential harmfulness to human health. Particulate material can be subdivided into: Coarse fraction: 2.5 to 10 microns. Capable of entering the lungs. Fine fraction: smaller than 2.5 microns. Capable of entering the alveoli, and continuing into the bloodstream.

In the Project, the final value after applying proposed weighting factors, reach values greater than the permissible limit for the emission of inhalable particulate matter (10 tons per year) established by the Atmospheric Decontamination and Pollution Prevention Plan, for all years of Project development.

What will be the real PM10 value after the application of bischofite solution as proposed? Who will take responsibility for this? What will happen if PM10 emissions in the area do not drop below PM10?

- The PHAM, according to available hydrological background information, including a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, and current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself

ANNEX 10

Why does the study mention 50 years? What will happen after the end of this period - will a new study be conducted, will the number of cubic meters that you plan to abstract be increased?

- In terms of winter road clearing, in view of the high-altitude situation. Certain sections of these roads remain closed during the winter season due to landslides, heavy precipitation, and intense snowfall. Annex 2 of the project.

How will you prevent the entry of private individuals into these areas, where the road to El Yeso has always been closed, as road conditions make access impossible, and the department of National Goods segments this area into risk zones?

Route G25 and Route G455 with a width of 7 m, if and only if the 31 kilometers of new road, with a roadway width of 10 m - what is the cause of the 3 extra meters of width in existing roads, as this action has certainly been implemented by the highways department? If these are only to be service roads, they will therefore be closed to the general public (tourists, for example) at the end of the project operations phase. Direct quote from the project documentation... "Only the service roads in the El Yeso - Lo Encañado will have access restricted, barring use by non-project vehicles during the project's operations phase - 4.2 kilometers".

for trucks carrying 12 to 15 cubic meters, as stated in the project documentation. Given that in this area Route G25 is on a slope with no view on either side, running both from San José de Maipo and from Santiago. My question is as to whether the entrances and exits of properties adjacent to this route must comply with the regulations imposed by the Regional Highways Department, and at this precise point there is no space available for the creation of parallel entrances 100 before the main gate.

- Bearing in mind the difference between the use of water rights and water concessions.

I would like to ask what you are talking about in Annex 20 of the Project.

1. Summary and conclusions.

Project impact on the system's sedimentation equilibrium...

In view of the absence of integrated management plans for aggregates extraction activities in the Maipo River, annual extraction rates appear to stand at the very limit of the what is sustainable for the watercourse, as deduced for background information reviewed. In this scenario, any perturbation to the system could lead to local riverbed erosion problems, as has occurred in the past due to overextraction during certain periods. Therefore, if the predicted reductions in sediment availability downstream of the Independent Intake implemented by the project come to pass, then although these variations are relatively minor, they may lead to local problems if measures are not taken to ensure more rational management of the watercourse and available water and aggregates resources. This management should clearly be conducted addressing the river basin as a whole, implemented by the competent authority.

It must be born in mind that whether or not the project goes ahead, in the long term the effects of the dam on the El Yeso River will come to be felt, leading to a state of static shielding, preventing this watercourse from contributing any significant quantity of sediment. This results in an estimated reduction of between 0.2 and 0.5 million tons per year in riverbed erosion and entrainment, for the situation without the current project. It is hard to estimate when this effect will be observed, particularly bearing in mind that after 43 years of operation of the dam, there is as yet no significant evidence of the formation of static shielding.

Finally, it should be mentioned that the morphological conditions of the Maipo River at the point where it leaves the valley are a consequence of the natural reduction in its sediment transport capacity, leading to the deposition of a proportion of its sediment load and the formation of multiple watercourses and islands. In view of its characteristics, the Maipo River (and all of the rivers not subject to intervention, in general) is not

static, but rather continually evolving, in a dynamic equilibrium where in flow rate, sedimentation, and river morphology are permanently interacting and modifying each other. The rate at which the system changes may be altered (and accelerated) if it is perturbed in any way, moving towards new equilibrium situations. Thus, if sediment transport rates into the system are changed, or in the event of excessive extraction of aggregates from the river, water flow may eventually lead to degradation in certain parts of the river system. However, these effects may be reduced or controlled through suitable management of the system; such management must necessarily be based on integrated perspective, including the entire river system through to the river mouth. In this sense, it can easily be seen that at present no rational management

system is applied to the extraction of aggregates in the Maipo River System. When the competent authority grants extraction permits based on local criteria, it fails to take into account the reaction of the system, in both spatial and temporal terms, and movement towards a new equilibrium situation.

On what grounds does the competent authority take the decision to grant permits based on local criteria? Does this refer to the criteria applied by the Metropolitan Regional Highways Department, now the Hydraulic Works Department? Or the criteria applied by the Mayor of San José de Maipo? Or do the criteria applied by the Municipal Council take precedence? Or the criteria that should now be applied by CONAMA, under Article 2 of Supreme Decree 95/2001?

"Environmental impact: alteration of the environment, directly or indirectly caused by a project or activity in a specific area."

Based on the definition of a direct impact, my impact as a sand man, as defined in the previous paragraph.

Who will take responsibility for the domino effect that will result from reduced supply of aggregates only in the Metropolitan Region? Will this be a repeat of the Transantiago project, in which whatever resources are present are taken away? This battle will last for less time!

Have you thought of what will happen if less sand is produced?

...As the river will bring less sand, there will therefore be less supply on the market. What will happen is that the cost per cubic meter will increase. At least the construction industry in the Metropolitan Region has not stagnated, and continues to show an upward trend.

At what time will the company bring together a meeting of those directly affected by this project? At what time will the company bring together a meeting of the sand producers in the Maipo River Valley between Km 190 and Km 150? I ask you, at what time will time be given to talk to me, either by Felipe Naranjo or by Carlos Mathiesen, about my case? This should clearly be before August 27, which is the end date for the citizen participation process.

What was Ms. Patricia Alvarado talking about when, during the citizen participation process held in San Gabriel she said that the river will bring in 15% less, and that from our point of view we would see this as 10 centimeters less, in visual terms.

Has this lady thought about what she is saying? She is stating that the Maipo River has a depth of less than one (1) meter. To be precise, she is saying that the river has a depth of 66.6 centimeters.

I demand that you read what you yourselves as a company have written in the project documentation. To give an example, in an average year the Maipo River

at San Alfonso carries approximately 151.83 cubic meters per second during the month of December. With the project in operation, it will carry 133.10 cubic meters per second. In percentage terms we are talking about 100% and 87.66% of this when the river is carrying a smaller quantity of water, or in other words a 12.34% lower flow rate. However, for example in August, the river carries 38.08 cubic meters per second in the situation without the project. In the situation

with the project this drops to 28.30; in percentage terms we are talking about 100% and 74.31%, in other words a 25.69% drop in flow rate. So as not to sound extremist, let's just take the QMA situation without the project, 72.63 cubic meters per second. QMA situation with the project, 58.51 cubic meters. That is, 19.44% less
In my case, the aggregates extraction months are November, December, January, and February.

Average monthly flow rates (average over 50 years from 1952 to 2002) according to Annex 20 of the Alto Maipo EIS. Maipo River at San Alfonso

Flow rates	November	December	January	February	
Average QMA					
With the Project	91.03	133.10	115.76	76.54	58.51
Without the Project	102.58	151.83	139.01	96.92	72.63
Percentage drop in flow with the Project	11.26%	12.33%	16.73%	21.02%	19.44%

According to average monthly flow rate percentages for other months. It emerges that during the ice melt months, the percentage drop in flow rate with the project will not be so high, but in the months when the Maipo River at San Alfonso carries the lowest flow rate (August) the drop in flow rate with the project represents a much higher percentage.

What I want to say is that water abstraction by the PHAM should vary between the ice melt months and other months, in a directly proportional manner (higher percentage abstraction when flow rate is higher). But according to your own plans it will be INVERSELY PROPORTION (a higher percentage abstraction when flow rate is lower). This makes no sense.

Ladies and gentlemen, perhaps the way you look at things I am an uneducated man. I only got through to the tenth grade at school, my father died when I was three and my mother died when I was 15 years old. Everything that I know I have learned every day of my life. With the experience that I have gained every day that I have lived, I read everything that passes through my hands. Not being an engineer, I would never make a statement as irresponsible as what Madam Patricia said. Do not think of us as small town folk with no education, or as moderately intelligent people who will not be able to understand a simple mathematical ratio.

Have some respect. Even though I am not engineers like you, I could still teach you a lot - including "Don't say something that you don't know about or if you are not 100% informed". Regarding: the concentration of solids in suspension as measured in the study presented in the EIS, Annex 20.

Direct quote:

To suitably analyze Table 7.3 it would be necessary to know the flow rates in each watercourse on the day that the measurements are taken, which information is not available. However, some conclusions can be drawn regarding the data collected. First is the major increase in solids in suspension observed in November, as against September and October, as a result of snow melt. This also reflects the relatively smaller amount produced in the basins associated with the Volcán, Yeso, and Colorado Rivers.

Just one paragraph above, two things have been admitted. First, for a suitable analysis, they have issued a judgment without possessing all of the information. Secondly, the snow melt season is the period when this study really ought to have been conducted, taking samples of all types (flow rate, sediment, solids in suspension or Qss, solid streambed erosion, sediment buildup, granulometric sampling, and topographic, bathymetric, and hydrographic surveys) at a number of measurement points.

Solid streambed erosion is expected in the annex, in part 7.2.

The predicted annual solid suspension entrainment was determined based on prior information, the results of which are summarized in Table 7.1. Table 7.2 shows solid suspension entrainment measured in the Volcán River in 1990, together with routine measurements conducted on the same day at the Maipo River station at San Alfonso and the Colorado River station upstream of the confluence with the Maipo River. Records of the Volcán River at Queltehues cover only a period running up to July 1, 1985, and it is therefore not possible to compare entrainment rates for this station. Despite the limitations of making a comparison of streambed erosion based on a single measurement, this can give an idea of the proportions

of sediment contributed by each watercourse. In this way, the contribution of the Colina Stream to the Maipo River at San Alfonso amounts to approximately 1%, and the contribution of the Volcán River to the Maipo River, at the confluence with the Colina Stream, is around 7%. This value can be compared to the total expected annual contribution, which in this case is 10%.

How can you say that predicted solid streambed erosion at Queltehues is 0.14 if you only have one value, as you yourselves admit in the previous paragraph?

I must once again insist. My statement, made in my previous 9-page citizen participation. I expect serious and real technical responses to my questions. My need, and my real demand, is:

- **Commitment by Alto Maipo AES Gener made to me regarding the direct impact that I will suffer as a result of the project, as the only sand producer whose works have received final acceptance.**
- **Serious responses based on serious studies, without assumptions regarding my questions.**
- **Rigor in all commitments that the EIS says will be made in these fields, and that they be recognized as environmental impact, for instance in the case of PM10.**
- **Rigor in all commitments that the PHAM EIS ought to accept affecting private individuals, as in my own case, as Annex 20 of the EIS has not yet even admitted what impact we will suffer.**

- **Recognition of persons and families that directly depend on aggregates as part of the workforce. We are not talking about very bad, bad, or good wages. We are talking about PERMANENT jobs.**

- **What will happen to supply and demand for aggregates in the Metropolitan Region when the PHAM is operation, and who will absorb the indirect costs associated with the project.**
- **Should the PHAM's water abstraction, in accordance with its rights, not be directly proportional to river flow rate levels? (higher average monthly flow rate, more water abstracted).**

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**). For information on water usage rights held by the Project, see **Table 2.3.4 in Chapter 2 of the EIS**.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5**.

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Qe zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned,

including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex**

17 of Addendum 1, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part. **AGU.06 Sediment**

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study** presented in **Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence. Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (**AGU.06.01**), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted.

It can be concluded that the Maipo River system can be managed such that, with the project operational, present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river.

In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level.

It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be

identical to those currently observed.

It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times of the year flow rate in the Maipo River watercourse drops

significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake Owned by Aguas Andinas, etc.

Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual abstraction rate at these intakes varies between 78 and 164 m³/second.

This situation clearly explains the high level of perturbation observed in the behavior of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years.

It is for this reason that the Project Owner asserts that its activities will have no impact on the current situation in the sand extraction sites located on the Maipo River.

AGU.06.04 Discharge effects

Water capture in advance of in-situ gravel removal leads first to a reduction in sediment load in water carried through the headworks to the turbine rooms, while the solid materials that is retained is returned to the river. At the point where water is discharged from the plants (Las Lajas area), water that has passed through the turbines - which contains a certain quantity of sediment - once again mixes with the water in the rivers, returning to its original conditions in terms of average sediment load (**Addendum, Section I, Question 28**).

At the point where water is returned to the Maipo River, in the Las Lajas area, there will be no degradation of the riverbed as it is composed entirely of rocks. It should be mentioned that the flow rate discharged from the PHAM at this point is always lower than the flow rate in the Maipo River just upstream.

During the operations phase of the Project, planned maintenance activities do not include any cleaning of tunnels and culverts. Inside the tunnels, the cross sectional area for water flow is small enough to prevent sedimentation. This is shown through the operation of the Alfalfa Plant for 20 years without any cleaning of the tunnels being included among maintenance activities.

The only operations that lead to the discharge of sediment are the discharge of gravel traps at the inlets, and the flushing of the sand traps, returning sediment to the river once a certain volume has built up within them. These operations are conducted intermittently and for short time periods (1 minute for sand traps, 10 minutes for gravel traps), at variable frequency depending on the season. For more information see the **Addendum, Section IV, Question 3**.

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

SLD Health Impact

The Project owner shall take responsibility for ensuring compliance with health and safety regulations, in order to prevent any possible risk to health and physical integrity for the inhabitants of San José Maipo as well as the persons working on the Project.

SLD.02 Atmospheric

Although the Project involves surface construction activities, which will lead to the emission of particulate matter, plans call for the implementation of a suite of mitigation measures that will result in a considerable reduction in emission, not only of the PHAM itself but also as against the baseline of current particulate emissions throughout the Project's area of influence. In addition to the above, these considerations should be evaluated bearing in mind the fact that most of the Project's works will be underground, not producing any emissions of particulate matter.

Conversely, given that most of the Project's works are to be located in high mountain areas, it can be stated that the prevailing ventilation conditions in this environment will facilitate the dispersion of dust, with a natural reduction in emissions during the winter season as a result of the additional moisture contributed by rain and snow precipitation.

For more information on emissions compensation measures, see **Annex 5 of the EIS**.

SLD.02.01 Pollutants

The Project's atmospheric emissions will correspond to dust suspended in the air as a result of earth moving activities (during excavations, loading and unloading, etc.), and the movement of vehicles at surface work areas. Emissions control will be conducted by means of:

- conservation of existing roads currently used by mine trucks,
- all new roads built will be treated with bischofite. Additional information provided in Section I, Question 42 and Section VI, Question 17, in the Addendum.
- use of tarpaulins covering truck loads,
- timely mechanical maintenance of equipment, machinery, and vehicles, and wetting of dusty surfaces

- use of wagons and belt conveyors for the removal of muck

Remark N° 207

Dear Sirs:

I am writing to you in my capacity as chairperson of the El Manzano Channel Irrigation Water Community in order to request that you bear in mind our requirements regarding the **Alto Maipo Project Environmental Impact Study presented by Gener**.

If you read the project documentation presented to CONAMA on May 22, you will see that its information on the project baseline, and the section on identification, prediction, and evaluation of environmental impacts to be generated in our area, are not mentioned - particularly with regard to our irrigation system. Similarly, it fails to address mitigation, much less establishing commitments to solve our problem, or compensation to which our community will have a right if it is affected.

Description of the problem: Our water abstraction system is located in the Colorado River at the 967 meter elevation level, and its structures were built in accordance with the regulations issued by the Directorate General of Water, to capture water from a natural overflow with a minimum height of 0.75 m in the water of the river. The PHAM plans to capture the water of the Colorado River in the Maitenes area, leaving the river with only an ecological flow rate of 0.7 m³/s (defined by the PHAM), plus our rights and the rights of other irrigation users such as the Maurino Channel. Under this situation it will become absolutely impossible for our intake to capture our water rights without the construction of new installations that permit this abstraction.

As an irrigation user community, we consider that **the construction costs pertaining to these works, and the maintenance costs accrued whenever they suffer any degree of total or partial destruction that prevents us from capturing the water over which we hold rights, should be payable in their entirety by the company that generates this impact**, and not the members of our community.

Thematic responses

Specific response

The Project Owner reiterates its commitment to ensuring that necessary infrastructure exists in the river to permit water to enter the channels at all times, in accordance with the rights granted and the availability of the river throughout the life of the PHAM project.

In conformity with commitments made in meetings held with the management of the El Manzano Channel at the offices of Gener between January and October 2008, Gener has agreed to underwrite the construction of new infrastructure necessary in order to ensure water capture from the Colorado River to which that community possesses legally granted rights, as well as to pay all additional maintenance costs that the community may incur as a consequence of the operation of the PHAM. Furthermore, Gener will pay all additional costs payable by the community to the DGA for corresponding permit applications.

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.02 Third party water

rights

The PHAM, making use of its legally constituted water usage rights, shall not affect the usufruct of water usage rights held by third parties (see **Section I, Question 40 of the Addendum**).

For information on water usage rights held by the Project, see

Table 2.3.4 in
**Chapter 2 of the
EIS.**

AGU.02.01 Irrigation

The main irrigation channels that draw their water from the Maipo River in the Project's area of influence - that it, in the first section of the river - are fed from intakes located near the Sirena Channel intake, located approximately 4.5 km upstream of the Independent Intake owned by the company Aguas Andinas, located in the Las Vertientes area. In view of the above, and considering that the point where the Project will return its water to the river system (Las Lajas area) is located upstream of the La Sirena Channel intake, it can be stated with confidence that the PHAM shall not affect the availability of water resources used for irrigation.

All works shown in the layout map included in **Chapter 5, Section 5.6.1.2, part c** are located upstream of the point where the Project will return its water to the river (Las Lajas area); this plan shows the results of the field survey conducted upstream of the PHAM discharge in the Las Lajas area, indicating all intake, channel, well, and other facilities for water abstraction in the El Volcán area, and the point where water will be returned by the Project to the river system. This information was sourced from the DGA Water Resource Information Center (map of intakes in the first section of the Maipo River, 1988), with on-site verification conducted in 2008.

The Project, making use of its legally-constituted water rights, shall not affect the current functioning of the channels, and channel users shall therefore not suffer detriment in making use of their own rights.

With regard to reductions in water flow rates in the river, and in accordance with observations made and studies conducted, these users (particularly in the cases of the Manzano and Maurino Channels) are not expected to experience any problems in capturing their water resources. During its construction phase, the Project plans to conduct a study to recommend a solution for the modification of the intakes of these two channels, and then to implement these recommendations (see **the Addendum, Section I, Question 40**)

AGU.02.02 **“Hanging”** **channels**

Gener has repeatedly issued declarations that it is aware that not only the works that it shall construct, but also the usage that it shall apply to in-stream water rights that it holds, shall have no effect whatsoever on the legitimate rights that various water user communities hold and make use of at the intakes of the channels that they possess and use to abstract water, over which they hold end user rights.

In view of the above, Gener maintains that it shall proceed to implement works to modify existing intakes within the Project's area of influence, such that the corresponding user communities can continue to make use of their water rights, with no impairment of any kind.

Remark N° 213

Real Available Water Resources

Baseline studies to define ecological flow rates, taking into account the geology, local soil studies, and impact on flora and fauna, would certainly arrive at much lower figures for real available water resources than those presented in project documentation - what is the real amount of energy that this project can generate?

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03 Baseline

The Baseline Study describes the current situation in the Project's area of influence, in order to be able to conduct an evaluation at a later date assessing impacts on aspects of the environment during construction and installation activities, activities and/or actions included in the Project, and subsequent operations.

The baseline studies for environmental components included in the EIS were derived from on-site information survey campaigns conducted during 2005, 2006, 2007, and 2008, as well as an exhaustive literature search analyzing specific studies and background information for relevant environmental components. Further information was compiled from aerial photographs, thematic maps, and information generated during Project engineering work. For more information, see **Annex 17** of the **Addendum**.

AGU.03.01 Water resources

The baseline studies used in determining existing water resources in the Project area are presented in **Chapter 5.3.5 of the EIS**.

This section presents information characterizing the basins and tributaries of the Volcán, Yeso, and Colorado Rivers, all in the context of the Maipo River Mountain Hydrological System. This characterization describes the current situation of the aspects that are of relevance in the environmental evaluation, and in particular the features related to flow dynamics and the usage of water resources.

A number of sources have been used in the preparation of this characterization: various environmental studies belonging to the Directorate-General of Water (DGA), Meteorological Department of Chile, and Aguas Andinas, as well as the Water Resource Analysis reports conducted by Gener, which are attached in Annex 13 of Addendum 1; this information was used to determine the monthly average flow rates for each of the rivers and streams involved in the Project.

For more in-depth information on water resource baseline information, see **Annexes 13 and 17 of the Addendum, and Section 5.7.1.3 of the EIS**.

AGU.03.02 Geology

The baseline studies used in determining the geological characteristics of the Project area are presented in **Section 5.3.6 of the EIS**. Additionally, the **hydro-geological baseline studies** for the Project area are presented in **Section 5.3.5.3 of the EIS**. Complementary information is also provided in **Annex 45 of the EIS**.

Both of these studies start with general background information on the area where the Project is to be installed, going on to present a detailed description of the geological and geomorphological characteristics of specific areas where Project works or activities are planned.

Complementary information is provided in **Annex 8 of the Addendum**.

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Qe) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different

sections of these rivers. These Qe zones are defined

in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfa and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3, and Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempo Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum**.

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neoporteria curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Lilolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4**.

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant

level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

PRO The Project

The PHAM is based on run-of-the-river hydroelectric energy generation, and therefore will feature no reservoirs - instead, it will generate electricity using available water, which will pass through the turbines and then be returned to the river.

This system avoids potential negative impacts on the environment arising from the construction of a dam, which can lead to the loss of fertile land or housing, and consequent effects on residents.

The advantage of this project is that most construction work will be implemented underground, using cutting edge construction technology and minimum surface intervention (**EIS, Chapter 1**). This feature also avoids air pollution that can be caused by excavation activities and earth movement, and leads to insignificant effects on road traffic.

The work sites will be located far away from settlements, with no effect caused by the annoyances that are typical of construction works.

Spoil and muck disposal sites, for the deposition of rock and earth excavated in the creation of tunnels and underground machine rooms, will be located at a number of sites that are not commonly frequented, minimizing their visual impact.

SUE Soil Impact

The baseline studies used in determining the soil characteristics of the Project area are presented in **Section 5.3.4 of the EIS**. Complementary information is provided in **response 32 xiii in Section 5 of Addendum 1**. In general, the District of San José de Maipo features low soil quality, as a result of its topographic and geomorphological characteristics. According to a study conducted by the Instituto de Investigaciones de Recursos Naturales (IREN) (Pérez, W.; Tamayo, A.: 1996), most soils in the District are classified as dryland non-arable soils.

In the land areas that form the Project's area of influence, and in particular in the upper reaches of the Yeso River and Volcán River sub-basins and in the middle reaches of the Colorado River, current usage patterns are strongly influenced by relief characteristics and conditions, and prevailing high mountain climate conditions, which bring about a number of limiting factors - including physical factors and accessibility factors - affecting the development of human activities.

Remark N° 214 Riverbed Erosion

The lack of water flow will bring about the degradation of the aggregates that form the beds of the rivers and streams that flow together to form the "Maipo", which will aggravate existing problems in bridge pilings, such as the case of the "Los Morros Bridge".

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study** presented in **Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (**AGU.06.01**), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted.

It can be concluded that the Maipo River system can be managed such that, With the Project operational , present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

AGU.06.03 Maipo River Sand Production

With regard to the extraction of aggregates in the Maipo River, during the operations phase of the PHAM, the Project will not modify current natural sediment (aggregates) transport dynamics occurring in the river.

In effect, under the natural dynamics, sediment transport takes place mainly in the months of November, December, and January, as a result of snow and ice melt in the high mountains, and it is during this season that variations in

flow rate in the Maipo River caused by the project stand at their lowest levels. The same behavior applies to winter season rises in river level.

It must be pointed out that the PHAM returns water to the Maipo River in the Las Lajas area, located upstream of the El Canelo zone, and therefore downstream of this point the river's flow dynamics with the project shall be identical to those currently observed.

It is of great importance to observe that currently, without the PHAM in operation, slightly downstream of the Las Vertientes area (in the La Obra stretch of the river), during certain times of the year flow rate in the Maipo River watercourse drops significantly, leaving the river bed dry, due to water abstraction at the following intakes: La Sirena Channel, San Carlos Channel, Independent Intake owned by Aguas Andinas, etc.

Average water abstraction flow rates attributable to the main drinking water and irrigation intakes, many of which also make use of hydroelectric power as a byproduct, but discounting the effects of existing hydroelectric plants on these channels that discharge directly into the intakes, amounts to 113 m³/second, which is equal to the average annual flow rate in the Maipo River at Las Vertientes. Depending on water availability, the annual abstraction rate at these intakes varies between 78 and 164 m³/second.

This situation clearly explains the high level of perturbation observed in the behavior of the Maipo River watercourse downstream of Las Vertientes, where the riverbed is dry except during periods of increased water level and in unusually wet years.

It is for this reason that the Project Owner asserts that its activities will have no impact on the current situation in the sand extraction sites located on the Maipo River.

AGU.06.04 Discharge effects

Water capture in advance of in-situ gravel removal leads first to a reduction in sediment load in water carried through the headworks to the turbine rooms, while the solid materials that is retained is returned to the river. At the point where water is discharged from the plants (Las Lajas area), water that has passed through the turbines - which contains a certain quantity of sediment - once again mixes with the water in the rivers, returning to its original conditions in terms of average sediment load (**Addendum, Section I, Question 28**).

At the point where water is returned to the Maipo River, in the Las Lajas area, there will be no degradation of the riverbed as it is composed entirely of rocks. It should be mentioned that the flow rate discharged from the PHAM at this point is always lower than the flow rate in the Maipo River just upstream.

During the operations phase of the Project, planned maintenance activities do not include any cleaning of tunnels and culverts. Inside the tunnels, the cross sectional area for water flow is small enough to prevent sedimentation. This is shown through the operation of the Alfalfa Plant for 20 years without any cleaning of the tunnels being included among maintenance activities.

The only operations that lead to the discharge of sediment are the discharge of gravel traps at the inlets, and the flushing of the sand traps, returning sediment to the river once a certain volume has built up within them. These operations are conducted intermittently and for short time periods (1 minute for sand traps, 10 minutes for gravel traps), at variable frequency depending on the season. For more information see the **Addendum, Section IV, Question 3**.

Remark N° 215 Riverbed Erosion

This will further exacerbate existing damage in the intakes of the channels, which are currently suspended for this very reason, without reaching their objective of connecting to the water flowing through the river.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the

rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.06 Sediment

Gener has conducted a sedimentation study on the Maipo River, whereunder it was determined that sediment load reduction figures relate to solid transport capacity, and not to the effective solid transport rate. Figures on effective transport rate are less certain due to the precariousness of information on aggregates extraction currently undertaken in the Maipo River. See the response to **question 22 b 9, Section I of the Addendum**.

Additionally, it must be borne in mind that methodologies used in the calculation of solid streambed wear in these rivers leads to uncertainties in the results amounting to 2 or more orders of magnitude, and therefore "a relatively broad range of values must be accepted for the purposes of analysis and design" (**chapter 6.1 of the Sedimentation Study presented in Annex 20 of the EIS**).

The discharge a flow rate of 65 m³/s into the Maipo River in the Las Lajas area will represent approximately 40% of the water naturally passing this point in the Maipo River, during the snow melt season (average annual flow rate for the October to March period at the Maipo stream gauge station at El Manzano is 161.36 m³/sec). In particular, during the month of January it will represent no more than 30% of River flow passing that point.

Conversely, even though the quantity of sediment in suspension is expected to drop in proportion to drop in flow rate, the values reported (page 4 of Annex 20 of the EIS) represent an upper limit, given that the analysis undertaken did not take into account the fact that the sand traps will remove up to 15% of solids in suspension in the inflowing water, as they are designed to trap particles larger than 0.15 mm in diameter (in the case of the Colorado and Olivares Rivers flowing into the Alfalfa Plant); 85% of sediment in water that reaches the sand trap is of a particle size smaller than 0.15 mm. Therefore, the water flow returned to the Maipo River should be expected to contain 85% of the sediment in suspension of naturally present in the watercourses from which the water is abstracted, the rest being returned to the original watercourses during periodic sand trap flushing.

As solid transport in suspension represents 27% of total solid transport, the real effects to be expected from the reduction in sediment in suspension amounts to a mere 1.8% drop in total solid transport in the Maipo River at Las Vertientes.

AGU.06.01 Sedimentation equilibrium

The analysis of the Project's effects on sediment transport dynamics was conducted taking into account two considerations:

1. Potential foreseen solid streambed wear (solid transport capacity) in the rivers, calculated on a theoretical basis in accordance with the hydraulic characteristics of these rivers and theoretical calculation relationships.
2. Effective solid transport rate (or real solid wear), calculated based on background information available for the creation of physical models (López y Tapia 1996) and information on rates of extraction of aggregates (CONAMA 1999 and MOP-REG 1998).

As would be expected, a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

It was determined that there would be no significant variation in real solid wear, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Nonetheless, downstream of Las Vertientes the sediment transport capacity is lower than sediment availability, due to the drastic reduction in water flow caused by existing intakes. This explains the concentration of aggregates extraction plants in this area.

The aforementioned assertions take into account:

- * Reduction in potential solid transport capacity in the Colorado River does not affect the availability of sediment in that river, given that it is greater than the actual quantity transported.
- * The level of aggregates extraction in the Maipo River downstream of Las Vertientes has been estimated at 2.4 million tons per year, representing less than 30% of sediment deposited in that zone.

AGU.06.02 Erosion

As explained in the previous thematic section, "**Sedimentation equilibrium**" (**AGU.06.01**), a reduction in flow rate in any watercourse results in a theoretical reduction in potential solid transport capacity.

Nonetheless, as stated in that section, there would be no significant variation in real solid wear/entrainment, comparing the situation as modeled with and without the Project, in the Project's area of influence.

Watercourse degradation problems and effects on certain Highway infrastructure installations, which can be observed currently downstream of Las Vertientes, are attributable more to the ways in which aggregates are extracted from river than to quantities extracted.

It can be concluded that the Maipo River system can be managed such that, With the Project operational , present aggregates extraction levels can be maintained, minimizing negative impacts on the watercourses and installations located in them.

Gener has offered to collaborate in the integrated studies currently being conducted by the Ministry of Public Works' Hydraulic Works Department.

Remark N° 223 Upper Maipo Basin Area Usage Flow Rate

The project plans establish a total water abstraction rate in the Upper Maipo Basin area of 27 m³/s. The question is: will the management of the El Yeso Reservoir cause any intervention?

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.02 Maximum flow rates to be abstracted

Table 2.3.6 presents the design flow rates of the intakes, while Table 2.3.7 shows maximum, average, and minimum flow rates for each section of conduit to be constructed as part of the Project; all of this information is to be found in **Chapter 2, Section 2.3.3.1 of the EIS.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In view of information contained in this study, which is provided in **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at least in part.

AGU.05 Drinking water supply

Construction works and/or activities involved in the project (roads, movement of materials, transport of different products, etc) shall have no effect or impact whatsoever on the quality or security/safety of water supply in the Maipo River system. During the construction phase, Project interventions affecting watercourses shall cause only temporary effects resulting from Earth moving during excavation and other construction activities. This intervention shall affect small areas over short time periods, as it shall last only during the period while these installations are under construction (see **Section 6.4.1.4 of the EIS and Section VII, Question 17, in the Addendum**).

During operations, the PHAM shall not affect the Laguna Negra-Lo Encañado and El Yeso Reservoir system, which is managed by the company Aguas Andinas S.A, in its capacity as holder of the drinking water concession for Santiago; nor shall the Project affect the operational dynamics of the drinking water supply system. Therefore, the implementation of the PHAM does not imply any impact whatsoever on the supply of drinking water (see **Section I, responses 27 and 29, in the Addendum**).

Furthermore, the water abstracted by the Project shall be returned to the river 5 km upstream of the Toma Independiente or Independent Intake, operated by the company Aguas Andinas S.A., which abstracts water for drinking water supply to the city of Santiago; therefore, the PHAM shall not affect normal operations of this system. The PHAM shall only affect the delivery point of water in the tributaries of the Maipo River; in other words, water that currently does not drain into the Maipo River shall not be incorporated into that river's total flow.

However, in the event that an incident may arise as a result of an accident during construction, such as accidental spillages or rock falls, the procedures described in the Contingency Plan shall be implemented, consisting of a suite of actions to solve associated problems. This plan is explained in detail in **Chapter 7 of the EIS, Section 7.2.5**.

Remark N° 224 Death of the Lung of Santiago

We live in a heavily polluted metropolis, particularly during the winter. Our escape is to visit the Cajón del Maipo Valley on weekends. A decline in water flow rates will affect the valley's green areas, and the possibility of breathing clean air just 30 minutes from the city.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

SLD Health Impact

The Project owner shall take responsibility for ensuring compliance with health and safety regulations, in order to prevent any possible risk to health and physical integrity for the inhabitants of San José Maipo as well as the persons working on the Project.

SLD.02 Atmospheric

Although the Project involves surface construction activities, which will lead to the emission of particulate matter, plans call for the implementation of a suite of mitigation measures that will result in a considerable reduction in emission, not only of the PHAM itself but also as against the baseline of current particulate emissions through the Project's area of influence. In addition to the above, these considerations should be evaluated bearing in mind the fact that most of the Project's works will be underground, not producing any emissions of particulate matter.

Conversely, given that most of the Project's works are to be located in high mountain areas, it can be stated that the prevailing ventilation conditions in this environment will facilitate the dispersion of dust, with a natural reduction in emissions during the winter season as a result of the additional moisture contributed by rain and snow precipitation.

For more information on emissions compensation measures, see **Annex 5 of the EIS.**

SUE Soil Impact

The baseline studies used in determining the soil characteristics of the Project area are presented in **Section 5.3.4 of the EIS.** Complementary information is provided in **response 32 xiii in Section 5 of Addendum 1.** In general, the District of San José de Maipo features low soil quality, as a result of its topographic and geomorphological characteristics. According to a study conducted by the Instituto de Investigaciones de Recursos Naturales (IREN) (Pérez, W.; Tamayo, A.: 1996), most soils in the District are classified as dryland non-arable soils.

In the land areas that form the Project's area of influence, and in particular in the upper reaches of the Yeso River and Volcán River sub-basins and in the middle reaches of the Colorado River, current usage patterns are strongly influenced by relief characteristics and conditions, and

prevailing high mountain climate conditions, which bring about a number of limiting factors - including physical factors and accessibility factors - affecting the development of human activities.

SUE.02 Soils, meadows, and wetlands

The Project Owner has conducted a number of studies with the aim of characterizing the vegetation of summer grazing areas (La Engorda) (see details in Addendum 1, Annex 6, and in Chapter 5 of the EIS), as well as flora and vegetation studies in the Project's area of influence (EIS, Chapter 5).

These studies contain information compiled in fieldwork campaigns conducted in Fall 2005, Spring 2006, November 2007, March 15 and 16, 2008, and September 2008, which add to the body of knowledge available regarding vegetation in these areas.

The Lo Encañado area shall be assigned a status of controlled access area for works contractors at all times: it shall not be subject to any intervention whatsoever. For more information on vegetation areas that could be affected by the construction works, and to learn about mitigation measures proposed by the Project Owner, you are advised to review Annex 42 of the EIS and Annex 6 of the Addendum.

With regard to environmental regulations that apply specifically to vegetation and plant life, the Project Owner shall be subject to:

Supreme Decree 366 (Exploitation of Tamarugo, Carob, Chañar, Guayacán, Aextoxicon, Charcoal, Acacia, Boldo, Maiten, Litre, Bollen, and Quillay). This legal instrument governs the felling of trees and bushes.

Supreme Decree 4363 and D.L 701 (Approving the Definitive Text of the Law on Woodland and Regulations on Forest Promotion).

Article 2 of the Woodland Law establishes an obligation that land classified as for preferential woodland land use, as well as natural and artificial woodlands, are subject to woodland management plans approved by the National Forestry Commission (CONAF). Furthermore, Article 21 of Decree Law 701 establishes that any felling or usage of native woodland shall be subject to the CONAF's prior approval of the corresponding management plan.

Decree 82 (Prohibiting the Felling of Trees and Bushes in Indicated Andean High Mountain and Foothill Areas)

Article 102 Sector Environmental Permit (Permit for the felling or exploitation of native woodland, in any type of land, or plantations located in land with preferential characteristics for woodland use).

For further information and analysis on the aforementioned regulations and permits, as applicable to the Project, as well as in terms of general aspects, compliance, and regulatory bodies, please see Sections 3.2.6 and 3.3.7 in Chapter 3 of the EIS.

Remark N° 225 Disappearance of Native Species

Native trees (Avellano and Maitén) use their roots to absorb deep underground water during times of drought. The reduced flow rate in the rivers will cause the disappearance of these species. Less than 10 years ago we experienced a drought that lasted almost 5 years. This event almost wiped out the Maitén trees in the area, while the Quillay trees survived thanks to their deep roots, and the existence of rivers and aquifers.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.03.03 Underground water

Underground water will not be affected in any way by the operation of the Project. This is the case because the underground water flow capacity in each sector of the aquifer associated with the Maipo River is much lower than the minimum flow running through each section of the river, and therefore under all circumstances the aquifers shall remain saturated. Thus, underground water sources present in the area shall also not be affected.

The PHAM plans to construct 70 km of tunnels, of which approximately 50 km correspond to headworks or hydraulic pressure tunnels, the remainder being access tunnels for use during construction of the project and for subsequent operation of the power plants (see **EIS Chapter 5, Section 5.3.5.3**).

Most of these tunnels have been designed to operate at variable internal pressures, with a maximum achieved at certain points of a little more than 450 m. The design requirement for these tunnels is that the lower limit of principal compression in the surrounding rock medium is always less than the operating pressure, such as to maintain a sufficient safety margin to prevent alterations in natural permeability dynamics through hidrojacking. In areas where this design principle is not guaranteed, the Project plans to install impermeable tunnel linings (**EIS, Annex 45.4**).

During the excavation of these tunnels, it is possible that the work front may have to pass through permeable rock strata - leading to seepages of water into the tunnel, the magnitude of which will depend on the permeability of the rock, the depth of the tunnel, and the level of the water table. In some areas, tunnel wall treatments may have to be applied in order to prevent water transfer into or out of the headworks tunnels.

The Project does not plan to make use of any water seepages that may arise, in the generation of electricity. Additionally, the overarching design principles underpinning the Project are oriented towards limiting seepages during construction, in order to establish suitable conditions for efficient tunnel excavation activities. The same principle applies to methods to limit the infiltration of water from the tunnels into the rock mass, thus avoiding water loss during operations.

Additionally, these procedures guarantee that any groundwater that may intercept the tunnels shall suffer no change in its natural hydrological dynamics, or impact on any foreign components or water other than the water entering the system (**EIS, Annex 45**). Special attention will be paid to the quality and characteristics of any water that may eventually return to the natural water system through the tunnel access windows, and therefore construction contracts will specify measurements that must be made and the treatment that shall be required for subsequent disposal of such water, in order to ensure compliance with the quality requirements for water discharge into natural watercourses, under regulations currently in force.

In the event of seepages of water at high temperature and possible acidic composition, it is important to make clear that in general there shall be no major differences in the methods used to render the tunnel walls impermeable. During all site surveys conducted, research boreholes and surface geological maps produced to date applying to the areas through which the tunnels will pass, no evidence whatsoever has been found to lead to any prediction of the presence of water at high temperatures, or with mineral or acidic contamination. As additional background information, during the construction of the Alfalfa Plant - with the excavation of 35 km of tunnels - no events similar to those indicated above occurred. Notwithstanding the above, the specification establish that, in locations located close to potentially critical areas, the contractor must drill survey boreholes of between 25 m and 30 m in length ahead of the tunnel work front, in order to gain early warning of seepage problems and thus be able to apply impermeable tunnel wall treatments as required. See **EIS, Annex 45.4**.

AGU.04 Water flow in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights

held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers.

The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River.

The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

F&F Biodiversity Impact

Flora and Fauna

The study conducted found evidence of the presence of 258 species of plants in the PHAM area of influence. Approximately 86 species of animal were recorded, including 3 species of amphibians, 9 reptiles, 70 bird species, and 4 mammals. These species counts are a sum total for the diversity of environments included in the study, and it must be taken into account that the areas subject to intervention are relatively small, and a large proportion of the total area is located in dry, high altitude habitat zones. A low level of aquatic fauna species richness and abundance was found, with a predominance of the introduced species *Salmo trutta* (Brown Trout) (**EIS, Chapter 5.4.3.3**).

F&F.02 Identification of species affected

Aquatic flora and fauna

3 fish species were recorded in the study area: *Salmo trutta* (brown trout), *Oncorhynchus mykiss* (rainbow trout) and *Trichomycterus areolatus* (Chilean Pencil Catfish or Bagre). The Bagre is a protected native species, and was recorded in the Maipo and Colorado Rivers (**EIS/5.4.3, and Addendum 1, Annex 17**). With regard to amphibian species facing conservation concerns, the presence of the following species has been recorded: the black spiny chest frog *Alsodes nodosus*, in the Aucayes Stream; the spiny frog in the El Volcán and Lo Encañado areas; and the four-eyed frog in the Colorado River area, the Quempe Stream, and the Lo Encañado Lake. These species inhabit a habitat comprising wet or moist areas, such as river bank areas and small pools.

A detailed analysis and identification of the aquatic plant species recorded in the Project's area of installation is to be found in the EIS, Chapter 5.4.3; this section also includes the results of sampling activities conducted.

For complementary and more in-depth information, see **Annex 17 of the Addendum.**

Terrestrial flora and vegetation

The following endangered species have been found to exist within the Project's area of influence: *Kageneckia angustifolia*; *Puya Berteroniana*; *Neoporteria curvispina*; *Laretia acaulis*; *Porlieria chilensis*; *Alstroemeria exerens*; and *Cryptocaria alba* (**EIS, Chapter 5.4**)

The Project calls for the replacement of woodland vegetation through the reforestation of land areas that are preferentially suitable for woodland coverage. The species listed for conservation that are not included in the woodland management plan are covered in the revegetation plans, which propose the replacement of 10 individuals for every one individual affected (**EIS, Chapter 7, Annex 7, and Annex 29**).

Terrestrial fauna

The following list presents the key species that have been recorded in the PHAM area and that face conservation concerns: Black Spiny Chest Frog (*Alsodes nodosus*), Four-eyed frog (*Pleurodema thaul*), Spiny Frog (*Bufo spinulosus*), Lo Valdés Lizard (*Liolaemus moradoensis*), Green Black Iguana (*Lilolaemus nigroviridis*), Racerunner or Chilean Iguana (*Callopistes palluma*), and Cururo (*Spalacopues cyanus*). For additional, complementary information, see **Addendum, Annex 4.**

F&F.02.01 Impact

Aquatic flora and fauna

During the construction phase, the impact of the Project on aquatic organisms shall be related specifically to the construction of intakes, siphons, bridges, and river protection measures, and online inasmuch as such works lead to the modification of the watercourse and affect water quality; in general, these events shall be temporary in nature, and of low magnitude.

In general, surface watercourses located within the Project area currently exhibit a significant level of human intervention, and as a result, populations of organisms consist mainly of introduced species (EIS 5.4.3). For more information, see Annex 17 of the Addendum.

The PHAM is expected to have no significant impact on this environmental system, as

construction activities and subsequent power plant operations shall not affect the continuity of water flow, and shall not cause significant effects on the habitat conditions of benthic communities, which shall maintain the same levels of abundance and species richness that they currently exhibit (EIS, Chapter 6).

Terrestrial Flora and Vegetation

Impact on terrestrial plant life will consist of the removal of individual plants and/or trees at the sites where works and installations are to be located. Given that most of the works constructed will be underground, and furthermore that the design of surface works has been conducted taking into account environmental criteria for siting, the removal of woodland and/or plant specimens of species listed for conservation will be minor (see EIS, Annexes 7 and 29).

Planned environmental management measures to mitigate/compensate for vegetation subject to intervention are presented in the woodland management plan and vegetation restoration plan (see EIS, Annexes 7 and 29).

Terrestrial fauna and birds

The impact on the terrestrial wildlife and birds shall consist of moving or displacing local animals - mainly reptiles and amphibians - due to the modification of their natural habitat and/or their being scared off by human activity. Over the course of the project, certain individuals may be lost, either those belonging to low-mobility species or those that lose their burrows or nesting sites. Nonetheless, based on past experience in similar projects, it is believed that most animals will tend to move away from areas subject to intervention as a result of Project works construction, moving into neighboring areas (EIS, Section 6.4.1.6).

No effects on birds are foreseen, beyond those indicated in the previous paragraph (EIS 5.4.2).

For more in-depth information on the wildlife management plan proposed by the Project Owner, see Annex 4 of the Addendum.

F&F.02.02 Mitigation

Aquatic flora and fauna

The Project calls for a suite of multi-purpose environmental management measures that aim to minimize its effects on living organisms, including: minimization of watercourse areas to be subject to intervention by prioritizing such works for late summer and early fall seasons (period of lowest flow rates), the adoption of special precautions to prevent accidental spillages into watercourses (prohibition of the storage of lubricant drums in or near watercourses, etc), and permanent maintenance of ecological flow rates.

For more detailed information, including technical documentation that complements the information described above, see Annex 17 of the Addendum.

Terrestrial Flora and Vegetation

In order to prevent and/or minimize the Project's effects on plant life, it plans to adopt a number of integrative measures: micro-routing in advance of starting work on-site, in order to identify specimens of plants listed in any conservation category and subject to impact; compensation with the planting of 10 specimens for every one destroyed, in the case of non-woodland species listed for conservation; implementation of a woodland management plan applicable to woodland areas, which describes its measures in accordance with Article 5 of the Woodland Law; implementation of vegetation restoration plans at muck disposal sites, encampments, artificial slopes, and tunnel access terraces (EIS, Annexes 7 and 29). More in-depth information on complementary measures is provided in Annex 6 of Addendum 1.

Terrestrial fauna

Specific wildlife environmental management measures have been proposed for each particular species, taking into account prior experience in the success of these measures in similar projects. These measures will be implemented in continual coordination with the Servicio Agrícola y Ganadero. Principal measures include: capture of individuals belonging to species of conservation interest for rescue and relocation; controlled perturbation actions; and habitat replacement. Other measures are based on the use of signage, training for Contractors, and contractual requirements for on-site supervision (see details in Section 6.4.1.6 of the EIS).

See Annex 4 of the Addendum for the native wildlife rescue and relocation plan.

Remark N° 226 Tourism in the Area

Tourism in the area provides employment for local residents. Lack of water due to reduction in rivers' flow rates will reduce the area's attractiveness. The employment that AES offers for residents of the valley is short term (perhaps 5 years?)

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information. The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on

tourism activities (water sports) undertaken in the Maipo River. Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.

AGU.04 Flow rates in rivers and streams

The Project plans to make use of water from rivers and streams in conformity with the water rights held by Gener and subject to maintaining ecological flow rates. Therefore, the source of impact shall be the consequent reduction in flow rates with the Project operational, modifying the natural - and in some cases, the regulated - water flow dynamics of certain rivers. The energy that will be generated by the Project is derived from water resources contributed by the Engorda, Colina, Las Placas, and El Morado Streams, which are tributaries of the Yeso River and the Colorado River. The power plants shall make use of water abstracted from the Upper Maipo River Basin, as well as water from the upper and middle reaches of the Colorado River, in the District of San José de Maipo, in the Santiago Metropolitan Region. The first of these power plants, Alfalfal II, is to be installed in the southern section of the Colorado River, downstream of the Alfalfal I Power Plant, and shall make use of water abstracted from the upper reaches of the Volcán River, as well as making use of water flowing out of the El Yeso Reservoir into the El Yeso River. The second of these plants, Las Lajas, is to be situated on the southern bank of the Colorado River, in the El Sauce area, and shall make use of water from the discharge outlets of the Alfalfal I and Alfalfal II power plants, as well as water taken from the middle reaches of the Colorado River.

For further information on the influence of the Project on tributaries in the area, see the **Addendum, Annex 17, and Section IV, Question 5.**

AGU.04.03 Ecological flow rates

The ecological flow rate is defined as the minimum value for water flow that must pass through a stretch of a river in order to maintain ecosystems. The operation and construction of power plants requires an ecological flow rate (Q_e) study, given that the intakes shall modify the natural conditions present in the rivers, making it necessary to identify the biological communities present in the river, as well as the ecological conditions under which they exist, and the minimum hydrodynamic requirements for their habitats to be maintained.

The analysis of the ecological flow rate of a river is conducted by means of the application of a suite of methodologies that have been defined through the implementation of advanced studies in this field, such as to derive a minimum rate of water flow that must pass through the different sections of these rivers. These Q_e zones are defined in the rivers that are to be subject to intervention by means of a systematic characterization of the watercourses, centered on conducting a hydrological, biological, morphological, and hydraulic characterization of them, with the aim of determining the areas that are most vulnerable to impact through reduction in river flow rates.

In the case of the PHAM, ecological flow rates have been established for the Yeso, Volcán, and Colorado Rivers, as well as the La Engorda, Colina, Las Placas and El Morado Streams.

It is important to underscore that the flow rate in the Maipo River features a series of regulated flow rates, such as the El Yeso Reservoir, and statistics available from these sources indicate that flow rate through the river drops to zero (0) during certain months. Other artificial modifications in the natural state of the hydrological system relate to the presence of the Alfalfal and Maitenes run-of-the-river power plants, which have been functional using water from the Colorado River since 1991 and 1923, respectively; as well as the Volcán and Queltehues plants, both operating in the Volcán River sub-basin since the 1940s.

Gener has conducted a reevaluation of ecological flow rates in each of the rivers and streams that will suffer a reduction in flow rate due to the operation of the PHAM. This study has been conducted through the identification of critical control sections, and the evaluation of areas known as Areas of Environmental Importance (AEI), in order to determine the minimum flow rate that must pass through these areas, taking into account aquatic organisms, human activities, water quality, and effects on the landscape.

To this end, a hydro-environmental study was applied to all of the rivers and streams concerned, including a description of the systems in terms of biological components (benthic wildlife, benthic autotrophs, zooplankton, phytoplankton, and fish species present) and abiotic components (stream morphology, flow depth, flow velocity, substrate type, and physical and chemical variables related to water quality). Elements related to human activities and landscape value are also included.

In light of the information presented in the aforementioned study, which is included as **Annex 17 of Addendum 1**, and taking into account levels of intervention currently found in the rivers of the basin - particularly the Yeso River - Gener considers it appropriate to apply the principle of habitability for low water summer flow rates, with an exceedence probability of 85%, additionally complemented with a Management Plan to help to neutralize existing environmental deficits, at

least in part.

CAL Impact on Quality of Life

All of the communities consulted by the Project Owner - El Canelo, El Manzano, Los Maitenes, El Alfalfal, San Gabriel, El Romeral, El Volcán, Lo Valdés, Baños Morales, and San José de Maipo - show certain levels of development in services linked to recreational and educational activities related to contact with and enjoyment of natural environments, as a result of the District's high value in this area.

In light of these characteristics, the Project has developed a suite of measures designed to minimize its impact through conserving the environment, such as: most infrastructure construction will be underground; maintenance of ecological flow rates; offsetting vegetation subject to impact; protections of meadows/wetlands; etc.

Similarly, the Project has enacted a suite of further measures to prevent interference with traditional livestock industries, as well as tourism and mountain sports.

Thus, the PHAM has adopted measures to avoid the disappearance or modification of land use patterns or type of land use, and loss in income during the construction and operations phases, as well as mitigating possible impacts on quality of life. For more information, please see the legislation affecting the Project (**EIS, Chapter 3**), the Environmental Management Plan (**EIS, Chapter 7**), and the Environmental Monitoring Plan (**EIS, Chapter 8**); together, these measures are designed to protect the PHAM's natural and human environment.

The Project will feature a very low percentage of surface works, none of which is located in populated areas or near to homes or settlements, with the exception of the settlement of Alfalfal. Additionally, the Project's environmental management activities will prevent it from causing a reduction in the area's environmental quality, with most of its impacts being either imperceptible, or present only during a time period limited to the works construction phase. Therefore, the Project will not bring about negative effects on environmental conditions that could result in a reduction in local residents' quality of life, or harm to the conceptual and/or symbolic features of the surroundings that are valued by families with long histories in the area, as well as those who have moved there more recently.

Chapter 5 of the EIS provides in-depth information on the "Human Environment" of the settlements that are located within the PHAM's area of influence: San José de Maipo, El Canelo, El Alfalfal, Los Maitenes, El Manzano, San Gabriel, Baños Morales, and Lo Valdés. Each of these settlements was the subject of studies addressing issues including principal economic activities, such as the livestock sector and activities linked to tourism and mountaineering, identifying the areas of access and times required. The population's social structure was also studied, as well as the characteristics of constructions and infrastructure, and coverage of basic services; all of this research permitted the estimation of the potential interference that the Project may cause in the area.

The encampments to be constructed are not expected to have any impact on the communities, as they will be located at a significant distance from settlements and subject to strict management of personnel lodged at them. The Project's transport activities will also not interfere with existing road traffic, as journey times along roads used will not be increased.

The evaluation program that has been conducted shows that the Project will not cause any negative impacts on the valuation of the area's constructions and settlements through any potential effects on quality of life linked to social and family connections, or security/safety, as the floating population of Project personnel will remain at the encampments and work sites, all of which are located at a significant distance from populated areas.

The Project will not cause any interference with traditional activities, and the studies have found no predicted impacts during its operations phase in any of the areas discussed, as the scope of the Project will be limited to the functioning of its works.

These statements are based on the opinions of experts in socio-environmental issues, and on experience from similar projects in the same area. In the case of Gener's Alfalfal Project, which was constructed in the Colorado River valley, it was found that during and after construction activities, the local community suffered no adverse effects associated with the loss of cultural characteristics.

Positive impacts have also been identified:

- i) relating to road improvement and maintenance, as well as the opening of new sections of road, which will improve connectivity and access, thus boosting property values and helping local families to continue to inhabit the more remote parts of the Project area, reducing emigration and thus strengthening social and family bonds;
- ii) Local Labor Hiring, and demand for complementary services related to works activities, fostering the dynamism of all activities in the District of San José de Maipo; iii) Improvement in quality of life for many families, as family members return to work in the District.

The company is currently engaged in talks with the principal social organizations of the district of San José de Maipo, evaluating monetary contributions that the company has publicly agreed to make to the community, as well as procedures and mechanisms for the usage of these funds and the duration of the program concerned.

In order to provide guarantees regarding of these measures, a Social Indicator Monitoring Program will be implemented, in order to control and verify the Project's impact on its human environment. By gaining solid, up-to-date knowledge of the types of impact, both positive and negative, that a project brings to its host communities, it is possible to make pertinent decisions both in order to leverage benefits and to mitigate or compensate for any harmful effects - a key element to underpin and preserve long term relationship of mutual wellbeing with surrounding communities. The principal characteristics of this program are specified in the **EIS, Chapter 8, Section 8.2.7** and in **EIS Annex 39**.

CAL.04 Fostering tourism in the area

From the perspective of the natural vocation of the district of San José de Maipo, tourism is a sector with growth potential, which must be addressed in an integrated manner and with an eye on the long term. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations.

The company will spearhead the development of a **Tourism Promotion Program**, particularly focusing on **Ecotourism**, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. The Project Owner will produce a **website** and editorial work, as well as the design of the first **edition of a tourist guide** for international visitors (bilingual), printing 5000 copies to support outreach and awareness building of the District of San José de Maipo as a national tourism resource.

Plans have also been drawn up for the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc., and the provision of **training in local tourism liaison for local residents**. **SOC Socio-Economic Impact**

Job creation plans for the district will take into account the concerns expressed by

community representatives during the advance citizen participation activities conducted, and will include local labor sourcing as one of the positive economic impacts that can be foreseen for the district.

In this regard, under the assumption that at the peak of hiring activities the PHAM will create an estimated 2500 new direct employment jobs during its construction phase, as well as indirect job creation in the district arising through the requirements of services for a project of this type, there will be an injection of capital into the district or local economy bringing benefits in areas such as construction, transport, and general services operating in the district.

During the operations phase, the power plants will pay taxes or license fees to the district, which, together with the fees currently paid, will amount to a figure close to CLP 180,000,000 per year.

SOC.01 Jobs in the District

Local labor availability is estimated based on figures from the Labor Brokerage and Information Office. This information will be made available to construction contractors so that they can preferentially hire local workers. According to information compiled at the Project Office in San José de Maipo, the project has registered a total of 980 potential project workers, of whom 390 are unemployed, broken down as follows:

Mine workers:	105
Carpenters, Builders, and Rebar Layers:	157
Heavy Machinery Operators:	131
Non-specialized day laborers:	39
Drivers:	87
Specialized technical personnel:	60
Welders:	26
Foremen and supervisors:	7
Graduate professionals:	20
Cleaning, security, and canteen workers:	120
Administrative personnel:	91
Other, misc.:	139

The average project workforce during the construction phase (5 years) is estimated at 2000 persons, and during the Citizen Participation process the company has agreed to ensure that an average of at least 500 local persons will be on the payroll during the construction of the Project.

SOC.01.01 Requirements

In view of the characteristics and scale of the Project, personnel with specific qualifications will be required for the operation and maintenance of plant machinery and equipment, during the operations phase. Conversely, during the Project Construction Phase, it is projected that labor requirements will create jobs not only for mining workers, but also for machinery operators, drivers, and both skilled and unskilled construction personnel, the latter working mainly as day laborers and assistants.

The population of the Project's area of direct influence has been found to possess levels of training and specialization (occupation as defined under the CIIU code) that shall permit them to access both skilled and unskilled work positions created by the Project.

SOC.01.02 Working conditions

To date no schedule exists specifying labor requirements for the full duration of the construction phase. Detailed information specifying jobs created under average and peak labor requirements, broken down by labor requirement dynamics for each encampment, will only be available once the Project Owner has tendered the works contracts.

During the operations phase, it is expected that personnel requirements will amount to approximately 80 positions available, required for power plant operations and maintenance activities. Unlike work positions created during the construction phase, the jobs created in the operations phase will be permanent (EIS, Chapter 6, Section 6.4.2.4).

The Project Owner will provide for coordination between the construction works contractors, the Labor Brokerage Office, and the Municipality of San José de Maipo, regarding local labor required and jobs sought. The PHAM has accepted a commitment to incentivize works contractors to prioritize local contracting of labor required.

No prior training is planned in advance of the Construction Phase. However, such training will form part of the programs implemented in the more advanced phases of the project.

SOC.04 Impact on economic activities in the area

Economic activities not linked to the primary sector have been identified, characterized, and evaluated, leading to an estimate of the project startup's impact on these activities. In terms of formal and informal activities related to recreational activities such as mountain climbing, tourism, camping, etc, the study specifies all trails used and the periodicity and seasonality of activities, providing background information on services offered or access to the natural environment for group or individual use linked to the education service. Further detail on mountain sports tourism is available in Annex 35 of the EIS, "Complementary survey of tourist attractions and tourism services in the District of San José de Maipo", and Annex 36 of the EIS, "Survey of high mountain activities".

In the context of the increased economic activity generated in the district through the situation of near-total employment, and enhanced development of services associated with the construction of the project, significant efforts were made to assess consequent reduction or loss of income through these activities.

A major issue addressed in the study was the determination of the periodicity of livestock and tourism activities, identifying how these will continue in areas where project works are undertaken or alongside these areas, during the construction and operations phases. In parallel, the study investigated possible increases in journey times between geographical points frequently used by formal and non-formal groups, as well as individuals, relating to livestock activities, tourism, and adventure sports.

TUR Tourism Scenery

The PHAM shall not directly or indirectly affect the course of tourism activities in the district; that is, it shall not stand in the way of such activities taking place in the manner in which they are currently conducted, or developing according to prevailing trends. The only possible effect lies in a modification in level of natural characteristics belonging to the areas immediately adjacent to the sites of surface works,

in those cases where these sites are located in areas that receive visitors. These effects shall not interfere in any way with activities conducted in the area, corresponding mainly to hiking, climbing, and mountaineering. The scope of this situation shall be extremely limited, being restricted to high and moderate elevation mountain areas. This situation applies to the works located in the lower parts of the Valle del Arenas or Valley of the Sands area, in Alto Volcán. For additional, more specific information, see **Chapter 6.4 of the EIS, Addendum 1, Section V, Question 21** and **Section VII, Question 19**.

TUR.02

Tourism impact

Impacts on tourism activities relate to potential annoyance caused to the users of public highways due to the movement of vehicles and the presence of work sites and works installations. It is expected that these impacts shall not be significant in terms of disincentivizing tourism and visits to the area. In the strictest terms, there shall be no interruption of activities themselves, or any deterioration in the tourism-related features of the area.

Given that most works are to be located underground and in high mountain areas, a "mining-style" working day shift pattern is to be used, which, combined with the suspension of project-related traffic flow during weekends as well as other measures designed to minimize impacts on traffic, shall ensure that any interference with tourism activities caused by the impact of the PHAM shall be of a low level of significance.

In view of the nature of activities under the operations phase of the PHAM, these activities are expected to have no impact on tourism activities (**see Chapter 6.4 of the EIS**).

Additionally, the Project Owner has proposed that is implement a program to incentivize tourism business development in the area:

Support for tourism business development

Gener has taken on a firm commitment to make use of its Maitenes Foundation (Annex 26 of the EIS) to make a concrete contribution to tourism promotion, as the sector shows major growth potential that must be addressed from an integrated perspective and adopting a long-term vision. As specified in the baseline study report, small tourism companies are present in the district, providing services with limited resources and on a small scale, or in totally informal operations. Under this approach, the company will spearhead the development of a Tourism Promotion Program, focusing particularly on Ecotourism, leveraging present experiences but most of all providing training, advisory services, and partial financing for new business initiatives coming from local providers in the sector. This approach includes the possibility of improving tourism infrastructure, such as hiking trails, mountain refuges, signage, etc.

Remark N° 227 Ecological flow rates

I believe that the ecological flow rates set by AES in the project documentation are totally insufficient to guarantee adequate irrigation for the valleys.

Thematic responses

AGU Water

The Project shall generate electricity using water taken from the Morado, Las Placas, La Engorda, and Colina streams, and from the Yeso and Colorado Rivers, over which the project owner holds instream water usage rights. These rights were granted by the DGA in accordance with the hydrology of each of the watercourses involved, establishing ecological flow rates for each of them, which must be respected by the Project. Gener is currently engaged in requesting adjustments to these rights to bring them into line with project requirements. Nonetheless, the Project's base line studies included a hydrological study of the watercourses involved, calculating flow rate times series for each of the rivers and streams to be used by the Project, over a period of 50 years. These studies were conducted based on prior hydrological studies, current flow rate data provided by the Dirección General de Aguas (DGA) and by Gener itself, as well as other information.

The studies included in the project's EIS indicate that the estimated reduction in flow rates shall not cause any impact on aquatic organisms or on biodiversity in areas surrounding the watercourses, or on Tourism activities (water sports) undertaken in the Maipo River.

Conversely, the Project Owner guarantees that it shall respect water rights held by third parties, and shall make any necessary adjustments to existing water intake works located within the project's area of influence such as to maintain their functionality, in all applicable cases.
